Abstract

In this article we study both left-invariant (convection-)diffusions and left-invariant Hamilton-Jacobi equations (erosions) on the space $\mathbb{R}^3 \ltimes S^2$ of 3D-positions and orientations naturally embedded in the group $SE(3)$ of 3D-rigid body movements. The general motivation for these (convection-)diffusions and erosions is to obtain crossing-preserving fiber enhancement on probability densities defined on the space of positions and orientations.

The linear left-invariant (convection-)diffusions are forward Kolmogorov equations of Brownian motions on $\mathbb{R}^3 \ltimes S^2$ and can be solved by $\mathbb{R}^3 \ltimes S^2$-convolution with the corresponding Green's functions or by a finite difference scheme. The left-invariant Hamilton-Jacobi equations are Bellman equations of cost processes on $\mathbb{R}^3 \ltimes S^2$ and they are solved by a morphological $\mathbb{R}^3 \ltimes S^2$-convolution with the corresponding Green's functions. We will reveal the remarkable analogy between these erosions/dilations and diffusions. Furthermore, we consider pseudo-linear scale spaces on the space of positions and orientations that combines dilation and diffusion in a single evolution.

In our design and analysis for appropriate linear, non-linear, morphological and pseudo-linear scale spaces on $\mathbb{R}^3 \ltimes S^2$ we employ the underlying differential geometry on $SE(3)$, where the frame of left-invariant vector fields serves as a moving frame of reference. Furthermore, we will present new and simpler finite difference schemes for our diffusions, which are clear improvements of our previous finite difference schemes.

We apply our theory to the enhancement of fibres in magnetic resonance imaging (MRI) techniques (HARDI and DTI) for imaging water diffusion processes in fibrous tissues such as brain white matter and muscles. We provide experiments of our crossing-preserving (non-linear) left-invariant evolutions on neural images of a human brain containing crossing fibers.

Keywords: Nonlinear diffusion, Lie groups, Hamilton-Jacobi equations, Partial differential equations, Sub-Riemannian geometry, Cartan Connections, Magnetic Resonance Imaging, High Angular Resolution Diffusion Imaging and Diffusion Tensor Imaging.

1 Introduction

Diffusion-Weighted Magnetic Resonance Imaging (DW-MRI) involves magnetic resonance techniques for non-invasively measuring local water diffusion inside tissue. Local water diffusion profiles reflect underlying biological fiber structure of the imaged area. For instance in the brain, diffusion is less constrained parallel to nerve fibers than perpendicular to them. In this way, the measurement of water diffusion gives information about the fiber structures present, which allows extraction of clinical information from these scans.

The diffusion of water molecules in tissue over time is described by a transition density \( y \mapsto p_t( Y_t = y \mid Y_0 = y_0) \) that reflects the probability density of finding a water molecule at time \( t > 0 \) at position \( y \in \mathbb{R}^3 \) at time \( t = 0 \). Here the family of random variables \( (Y_t)_{t \geq 0} \) (stochastic process) with joint state space \( \mathbb{R}^3 \) reflects the distribution of water molecules over time. The function \( p_t \) can be directly related to MRI signal attenuation of Diffusion-Weighted image sequences, so can be estimated given enough measurements. The exact methods to do this are described by e.g. Alexander [3]. Diffusion tensor imaging (DTI), introduced by Basser et al. [11], assumes that \( p_t \) can be described for each position \( y \in \mathbb{R}^3 \) by an anisotropic Gaussian function. So

\[
p_t(Y_t = y' \mid Y_0 = y) = \frac{1}{(4\pi t)^{\frac{3}{2}} \sqrt{\det D(y)}} e^{-\frac{(y' - y)^T D(y)^{-1} (y' - y)}{4t}},
\]

where \( D \) is a tensor field of positive definite symmetric tensors on \( \mathbb{R}^3 \). In a DTI-visualization one plots the surfaces

\[
y + \{ v \in \mathbb{R}^3 \mid v^T D^{-1}(y)v = \mu^2 \},
\]

where \( \mu > 0 \) is fixed and \( y \in \Omega \) with \( \Omega \) some compact subset of \( \mathbb{R}^3 \). From now on we refer to these ellipsoidal surfaces as DTI-glyphs. The drawback of this anisotropic Gaussian approximation in DTI is the limited angular resolution of the corresponding probability density \( U : \mathbb{R}^3 \times S^2 \to \mathbb{R}^+ \) on positions and orientations

\[
U(y,n) = \frac{3}{4\pi} \int_{\Omega} \text{trace}(D(y'))(dy')n^T D(y)n, \quad y \in \mathbb{R}^3, n \in S^2,
\]

and thereby unprocessed DTI is not capable of representing crossing, kissing or diverging fibers, cf. [3].

High Angular Resolution Diffusion Imaging (HARDI) is another recent magnetic resonance imaging technique for imaging water diffusion processes in fibrous tissues such as brain white matter and muscles. HARDI provides for each position in \( \mathbb{R}^3 \) and for each orientation an MRI signal attenuation profile, which can be related to the local diffusivity of water molecules in the corresponding direction. Typically, in HARDI modeling the Fourier transform of the estimated transition densities is considered at a fixed characteristic radius (generally known as the b-value), [22]. As a result, HARDI images are distributions \( (y,n) \mapsto U(y,n) \) over positions and orientations, which are often normalized per position. HARDI is not restricted to functions on the 2-sphere induced by a quadratic form and is capable of reflecting crossing information, see Figure 1, where we visualize HARDI by glyph visualization as defined below.

**Definition 1** A glyph of a distribution \( U : \mathbb{R}^3 \times S^2 \to \mathbb{R}^+ \) on positions and orientations is a surface \( S_\mu(U)(y) = \{ y + \mu U(y,n) n \mid n \in S^2 \} \subset \mathbb{R}^3 \) for some \( y \in \mathbb{R}^3 \) and \( \mu > 0 \). A glyph visualization of the distribution \( U : \mathbb{R}^3 \times S^2 \to \mathbb{R}^+ \) is a visualization of a field \( y \mapsto S_\mu(U)(y) \) of glyphs, where \( \mu > 0 \) is a suitable constant.

For the purpose of detection and visualization of biological fibers, DTI and HARDI data enhancement should maintain fiber junctions and crossings, while reducing high frequency noise in the joined domain of positions and orientations. Promising research has been done on constructing diffusion/regularization processes on the 2-sphere defined at each spatial locus separately [21, 36, 37, 65] as an essential pre-processing step for robust fiber tracking. In these approaches position and orientation space are decoupled, and diffusion is only performed over the angular part, disregarding spatial context. Consequently, these methods are inadequate for spatial denoising and enhancement, and tend to fail precisely at the interesting locations where fibres cross or bifurcate.
In contrast to previous work on diffusion of DW-MRI [21, 36, 37, 65, 56], we consider both the spatial and the orientational part to be included in the domain, so a HARDI dataset is considered as a function \( U : \mathbb{R}^3 \times S^2 \rightarrow \mathbb{R} \). Furthermore, we explicitly employ the proper underlying group structure, that naturally arises by embedding the coupled space of positions and orientations \( \mathbb{R}^3 \times S^2 \) into the group \( SE(3) = \mathbb{R}^3 \rightacts SO(3) \) of 3D-rigid motions. The relevance of group theory in DTI/HARDI (DW-MRI) imaging has also been stressed in promising and well-founded recent works [43, 44, 45]. However these works rely on bi-invariant Riemannian metrics on compact groups (such as \( SO(3) \)) and in our case the group \( SE(3) \) is neither compact nor does it permit a bi-invariant metric [6, 30].

Throughout this article we use the following identification between the DW-MRI data \((y, n) \rightarrow U(y, n)\) and functions \( \tilde{U} : SE(3) \rightarrow \mathbb{R} \) given by
\[
\tilde{U}(y, R) = U(y, Re_z).
\]
(3)

By definition one has \( \tilde{U}(y, RR_{e_z, \alpha}) = \tilde{U}(y, R) \) for all \( \alpha \in [0, 2\pi) \), where \( R_{e_z, \alpha} \) is the counterclockwise rotation around \( e_z \) by angle \( \alpha \).

In general the advantage of our approach on \( SE(3) \) is that we can enhance the original HARDI/DTI data using simultaneously orientational and spatial neighborhood information, which potentially leads to improved enhancement and detection algorithms, [33, 59, 58]. See Figure 2 where fast practical implementations [59] of the theory developed in [33, ch:8.2] have been applied. The potential clinical impact is evident: By hypo-elliptic diffusions on \( \mathbb{R}^3 \times S^2 \) one can generate distributions from DTI that are similar to HARDI-modeling as recently reported by Prčkovska et al. [58]. This allows a reduction of scanning directions in areas where the random walks processes that underly hypo-elliptic diffusion [33, ch:4.2] on \( \mathbb{R}^3 \times S^2 \) yield reasonable fiber extrapolations. Experiments on neural DW-MRI images containing crossing fibers of the corpus callosum and corona radiata show that extrapolation of DTI (via hypo-elliptic diffusion) can cope with HARDI for a whole range of reasonable \( b \)-values, [58]. See Figure 2. However, on the locations of crossings HARDI in principle produces more detailed information than extrapolated DTI and application
Figure 2: DTI and HARDI data containing fibers of the corpus callosum and the corona radiata in a human brain with $b$-value $1000\, s/mm^2$ on voxels of $(2\, mm)^3$, cf. [58]. We visualize a $10 \times 16$-slice (162 samples on $S^2$ using icosahedron tessellations) of interest from $104 \times 104 \times 10 \times (162 \times 3)$ datasets. Top row, region of interest with fractional anisotropy intensities with colorcoded DTI-principal directions. Middle row, DTI data $U$ (49 scanned orientations) visualized according to Eq. (1) respectively Def. 1. Bottom row: HARDI data (Q-ball with $l \leq 4$, [22]) of the same region, processed DTI data $\Phi_t(U)$. For the sake of visualization we applied min-max normalization of $n \mapsto \Phi_t(U)(y,n)$ for all positions $y$. For parameter settings of the hypo-elliptic diffusion operator $\Phi_t$, see Section 6, Eq. (49).

of the same hypo-elliptic diffusion on HARDI removes spurious crossings that arise in HARDI, see Figure 3 and the recent work [59].

In this article we will build on the recent previous work [58, 33, 59], and we address the following open issues that arise immediately from these works:

- Can we adapt the diffusion on $\mathbb{R}^3 \rtimes S^2$ locally to the initial HARDI/DTI image?
- Can we apply left-invariant Hamilton-Jacobi equations (erosions) to sharpen the data without grey-scale transformations (squaring) needed in our previous work ?
- Can we classify the viscosity solutions of these left-invariant Hamilton-Jacobi equations?
- Can we find analytic approximations for viscosity solutions of these left-invariant Hamilton-Jacobi equations on $\mathbb{R}^3 \rtimes S^2$, likewise the analytic approximations we derived for linear left-invariant diffusions, cf. [33, ch:6.2]?
- Can we relate alternations of greyscale transformations and linear diffusions to alternations of linear diffusions and erosions?
Figure 3: Same settings as Fig. 2, except for different $b$-value and a different region of interest and the hypo-elliptic diffusion, Eq. (49), is applied to the HARDI dataset.

- The resolvent Green’s functions of the direction process on $\mathbb{R}^3 \rtimes S^2$ contain singularities at the origin, [33, ch: 6.1, Fig. 8]. Can we overcome this complication in our algorithms for the direction process and can we analyze iterations of multiple time integrated direction process to control the filling of gaps?

- Can we combine left-invariant diffusions and left-invariant dilations/erosions in a single pseudo-linear scale space on $\mathbb{R}^3 \rtimes S^2$, generalizing the approach by Florack et al. [35] for greyscale images to DW-MRI images?

- Can we avoid spherical harmonic transforms and the sensitive regularization parameter $t_{\text{reg}}$ [33, ch: 7.1, 7.2] in our finite difference schemes and obtain both faster and simpler numerical approximations of the left-invariant vector fields?

To address these issues, we introduce besides linear scale spaces, morphological scale spaces and pseudo-linear scale spaces $(y, n, t) \mapsto W(y, n, t)$, for all $y \in \mathbb{R}^3, n \in S^2, t > 0$, defined on $(\mathbb{R}^3 \rtimes S^2) \times \mathbb{R}^+$, where we use the input DW-MRI image as initial condition $W(y, n, 0) = U(y, n)$.

To get a preview of how these approaches perform on the same neural DTI dataset (different slice) considered in [58], see Fig. 5, where we used

$$V(U)(y, n) = \left( \frac{U(y, n) - U_{\text{min}}(y)}{U_{\text{max}}(y) - U_{\text{min}}(y)} \right)^2, \text{ with } U_{\text{max}}(y) = \max_{n \in S^2} \{ U(y, n) \},$$

Typically, if linear diffusions are directly applied to DTI the fibers visible in DTI are propagated in too many directions. Therefore we combined these diffusions with monotonic transformations in the codomain $\mathbb{R}^+$, such as squaring input and output cf. [33, 59, 58]. Visually, this produces anatomically plausible results, cf. Fig. 2 and Fig. 3, but does not allow large global variations in the data. This is often problematic around ventricle areas in the brain, where the glyphs are usually larger than those along the fibers, as can be seen in the top row of Fig. 5. In order to achieve a better way of sharpening the data where global maxima do not dominate the sharpening of the data, cf. Fig. 4, we propose morphological scale spaces on $\mathbb{R}^3 \rtimes S^2$ where transport takes place orthogonal to the fibers, both spatially and spherically, see Fig. 6. The result of such an erosion after application of a linear diffusion is depicted down left in Fig. 5, where the diffusion has created crossings in the fibers and where the erosion has visually sharpened the fibers. Simultaneous dilation and diffusion can be achieved in a pseudo-linear scale space that conjugates a diffusion with a
specific grey-value transformation. An experiment of applying such a left-invariant pseudo-linear scale space to DTI-data is given up-right in Figure 5. Regarding the numerics of the evolutions we mainly consider the left-invariant finite difference approach in [33, ch:7], as an alternative to the analytic kernel implementations in [33, ch:8.2] and [58, 59]. Here we avoid the discrete spherical Harmonic transforms [33], but use fast precomputed linear interpolations instead as our finite difference schemes are of first order accuracy anyway. Regarding the Hamilton-Jacobi equations involved in morphological and pseudo-linear scale spaces we have, akin to the linear left-invariant diffusions [33, ch:7], two options: analytic morphological \( R^3 \rtimes S^2 \)-convolutions and finite differences. Regarding fast computation on sparse grids the second approach is preferable. Regarding geometric analysis the first approach is preferable.

We show that our morphological \( R^3 \rtimes S^2 \)-convolutions with analytical morphological Green’s functions are the unique viscosity solutions of the corresponding Hamilton-Jacobi equations on \( R^3 \rtimes S^2 \). Thereby, we generalize the results in [34, ch:10], [52] (on the Heisenberg group) to Hamilton-Jacobi equations on the space \( R^3 \rtimes S^2 \) of positions and orientations.

Evolutions on HARDI-DTI must commute with all rotations and translations. Therefore evolutions on HARDI and DTI and underlying metric (tensors) are expressed in a local frame of reference attached to fiber fragments. This frame \( \{\mathcal{A}_1, \ldots, \mathcal{A}_6\} \) consists of 6 left-invariant vector fields on \( SE(3) \), given by

\[
\mathcal{A}_i \hat{U}(y, R) = \lim_{h \downarrow 0} \frac{U( (y, R) e^{h\mathcal{A}_i} ) - U(( y, R ) e^{-h\mathcal{A}_i} )}{2h}
\]

where \( \{\mathcal{A}_1, \ldots, \mathcal{A}_6\} \) is the basis for the Lie-algebra at the unity element and \( T_e(SE(3)) \ni A \to e^A \in SE(3) \) is the exponential map in \( SE(3) \) and where the group product on \( SE(3) \) is given by

\[
(x, R)(x', R') = (x + Rx', RR'),
\]

for all positions \( x, x' \in \mathbb{R}^3 \) and rotations \( R, R' \in SO(3) \). The details will follow in Section 4, see also [33, ch:3.3, Eq. 23–25] and [33, ch:7] for implementation. In order to provide a relevant intuitive preview of this moving frame of reference we refer to Fig. 6. The associated left-invariant dual frame \( \{d\mathcal{A}_1, \ldots, d\mathcal{A}_6\} \) is uniquely determined by

\[
(d\mathcal{A}_i, A_j) := d\mathcal{A}_i(A_j) = \delta^i_j, \quad i,j = 1, \ldots, 6,
\]

where \( \delta^i_j = 1 \) if \( i = j \) and zero else. Then all possible left-invariant metrics are given by

\[
G(y, R_n) = \sum_{i,j=1}^6 g_{ij} d\mathcal{A}_i|_{(y, R_n)} \otimes d\mathcal{A}_j|_{(y, R_n)},
\]

where \( y \in \mathbb{R}^3, n \in S^2 \) and where \( R_n \in SO(3) \) is any rotation that maps \( e_z = (0, 0, 1)^T \) onto the normal \( n \in S^2 \), i.e.

\[
R_n e_z = n.
\]

and where \( g_{ij} \in \mathbb{C} \). Necessary and sufficient conditions on \( g_{ij} \) to induce a well-defined left-invariant metric on the quotient \( \mathbb{R}^3 \rtimes S^2 = (SE(3)/(\{0\} \times SO(2))) \) can be found in Appendix E. It turns out that the matrix \([g_{ij}]\) must be
Figure 5: DTI data of corpus callosum and corona radiata fibers in a human brain with b-value $1000 \text{s/mm}^2$ on voxels of $(2 \text{mm})^3$. Top row: DTI-visualization according to Eq. (1). The yellow box contains $13 \times 22 \times 10$ glyphs with 162 orientations of the input DTI-data depicted in the left image of the middle row. This input-DTI image $U$ is visualized using Eq. (2) and Rician noise $\eta_r$ [33, Eq. 90] with $\sigma = 10^{-4}$ has been included. Operator $V$ is defined in Eq. (4). Middle row, right: output of finite difference scheme pseudo-linear scale space (for parameters see Section 11). Bottom row, left: output erosion, Eq. (135) after hypo-elliptic diffusion, Eq. (49) with $(D_{44} = 0.04, D_{33} = 1, t = 1)$, right: output of non-linear adaptive diffusions discussed in [20] with $D_{44} = 0.01$. All evolutions commute with rotations and translations and are implemented by finite differences (Section 12) with time $t$ and stepsize $\Delta t$. 

\[
b = 1000 \text{s/mm}^2, \quad N_0 = 49
\]

\[
V((\text{DTI})^2 + \eta_r)
\]

\[
t = 1, \quad D_{33} = 1, \quad D_{44} = 0.04, \quad C = 4, \quad \Delta t = 0.01
\]
Consequently, the metric is parameterized by the values \( D \) to rotations in the isotropic planes depicted in Figure 6) and with the differential operators on \( \mathbb{R} \) it is well-defined on \( \mathbb{R} \). In \([33, \text{ch:6.2}]\) we have analytically approximated the hypo-elliptic diffusion kernels for both the direction process and \( e \). The corresponding metric tensor on the quotient \( \mathbb{R}^3 \times S^2 = (\text{SE}(3)/\langle \{0\} \times SO(2) \rangle) \) is given by

\[
G^{D^{31}D^{32}D^{41}44}_{(y,n)} \left( \sum_{i=1}^{5} c^i A^i|_{(y,n)} \right)^2 \left( \sum_{j=1}^{5} d^j A^j|_{(y,n)} \right) = G^{D^{31}D^{32}D^{41}44}_{(y,R_n)} \left( \sum_{i=1}^{5} c^i A^i|_{(y,n)} \right) \left( \sum_{j=1}^{5} d^j A^j|_{(y,n)} \right) = \frac{1}{D^{33}} (c^i d^i) + \frac{1}{D^{44}} (c^i d^i) + \frac{1}{D^5} (c^i d^i + c^i d^i). \tag{10}
\]

It is well-defined on \( \mathbb{R}^3 \times S^2 \) as the choice of \( R_n \). Eq. (9), does not matter (right-multiplication with \( R_{e_\alpha} \)) boils down to rotations in the isotropic planes depicted in Figure 6) and with the differential operators on \( \mathbb{R}^3 \times S^2 \):

\[
(A_j|_{(y,n)} U)(y,n) = \lim_{h \to 0} U(y+hR_n e_j) - U(y-hR_n e_j),
\]

\[
(A_{3+j}|_{(y,n)} U)(y,n) = \lim_{h \to 0} U(y,(R_n e_j,h) e_j) - U(y,(R_n e_j,-h) e_j), \quad j = 1, 2, 3,
\]

where \( R_{e_j} \) denotes the counter-clockwise rotation around axis \( e_j \) by angle \( h \), with \( e_1 = (1,0,0) \), \( e_2 = (0,1,0) \), \( e_3 = (0,0,1) \), which (except for \( A_3 \)) do depend on the choice of \( R_n \) satisfying Eq. (9).

In \([33, \text{ch:6.2}]\) we have analytically approximated the hypo-elliptic diffusion kernels for both the direction process and Brownian motion on the sub-Riemannian manifold (or contact manifold \([12] \) \((SE(3), dA^1, dA^2, dA^6)\)) using contraction towards a nilpotent group. For the erosions we employ a similar type of technique to analytically approximate the erosion (and dilation) kernels that describe the growth of balls in the sub-Riemannian manifold \((SE(3), dA^3, dA^6)\).

A sub-Riemannian manifold is a Riemannian manifold with the extra constraint that tangent-vectors to curves in that Riemannian manifold are not allowed to use certain subspaces of the tangent space. For example, curves in \((SE(3), dA^1, dA^2, dA^6)\) are curves \( \hat{\gamma} : [0, L] \to SE(3) \) with the constraint

\[
\langle dA^1|_{\hat{\gamma}(s)}, \hat{\gamma}(s) \rangle = \langle dA^2|_{\hat{\gamma}(s)}, \hat{\gamma}(s) \rangle = \langle dA^6|_{\hat{\gamma}(s)}, \hat{\gamma}(s) \rangle = 0, \tag{11}
\]

for all \( s \in [0, L], L > 0 \). Note that Eq. (11) implies that

\[
\hat{\gamma}(s) = \langle dA^3|_{\hat{\gamma}(s)}, \hat{\gamma}(s) \rangle A_3|_{\hat{\gamma}(s)} + \langle dA^4|_{\hat{\gamma}(s)}, \hat{\gamma}(s) \rangle A_4|_{\hat{\gamma}(s)} + \langle dA^5|_{\hat{\gamma}(s)}, \hat{\gamma}(s) \rangle A_5|_{\hat{\gamma}(s)}.
\]
Curves satisfying (11) are called horizontal curves and we visualized a horizontal curve in Figure 6. For further details on differential geometry in (sub-Riemannian manifolds within) \( SE(3) \) and \( \mathbb{R}^3 \times S^2 \) see Appendices A, B and C, E and G.

### 1.1 Outline of the article

This paper is organized as follows. In section 2 we will explain the embedding of the coupled space of positions and orientations \( \mathbb{R}^3 \times S^2 \) into \( SE(3) \). In section 3 we explain why operators on DW-MRI must be left-invariant and we consider, as an example, convolutions on \( \mathbb{R}^3 \times S^2 \). In section 4 we construct the left-invariant vector fields on \( SE(3) \). In general there are two ways of considering vector fields. Either one considers them as differential operators on smooth locally defined functions, or one considers them as tangent vectors to equivalent classes of curves. These two viewpoints are equivalent, for a formal proof see [7, Prop. 2.4]. Throughout this article we will consider them as differential operators and use them as reference frame, cf. Fig 6, in our evolution equations in later sections. Then in Section 5 we consider morphological convolutions on \( \mathbb{R}^3 \times S^2 \).

In Section 6 we consider all possible linear left-invariant diffusions that are solved by \( \mathbb{R}^3 \times S^2 \)-convolution (Section 3) with the corresponding Green’s function. Subsequently, in Section 7 we consider their morphological counter part: left-invariant Hamilton-Jacobi equations (i.e. erosions), the viscosity solutions of which are given by morphological convolution, cf. Section 5, with the corresponding (morphological) Green’s function. This latter result is a new fundamental mathematical result, a detailed proof is given in Appendix B.

Subsequently, in Section 8 and in Section 9 we provide respectively the underlying probability theory and the underlying Cartan differential geometry of the evolutions considered in Section 5 and Section 6. Then in Section 10 we derive analytic approximations for the Green’s functions of both the linear and the morphological evolutions on \( \mathbb{R}^3 \times S^2 \). Section 11 deals with pseudo linear scale spaces which are evolutions that combine the non-linear generator of erosions with the generator of diffusion in a single generator.

Section 12 deals with the numerics of the (convection)-diffusions, the Hamilton-Jacobi equations and the pseudo linear scale spaces evolutions. Section 13 summarizes our work on adaptive left-invariant diffusions on DW-MRI data. for more details we refer to the Master thesis by Eric Creusen [20]. Finally, we provide experiments in Section 14.

### 2 The Embedding of \( \mathbb{R}^3 \times S^2 \) into \( SE(3) \)

In order to generalize our previous work on line/contour-enhancement via left-invariant diffusions on invertible orientation scores of 2D-images we first investigate the group structure on the domain of an HARDI image. Just like orientation scores are scalar-valued functions on the coupled space of 2D-positions and orientations, i.e. the 2D-Euclidean motion group, HARDI images are scalar-valued functions on the coupled space of 3D-positions and orientations. This generalization involves some technicalities since the 2-sphere \( S^2 = \{ x \in \mathbb{R}^3 \mid \|x\| = 1 \} \) is not a Lie-group proper\(^1\) in contrast to the 1-sphere \( S^1 = \{ x \in \mathbb{R}^2 \mid \|x\| = 1 \} \). To overcome this problem we will embed \( \mathbb{R}^3 \times S^2 \) into \( SE(3) \) which is the group of 3D-rotations and translations (i.e. the group of 3D-rigid motions). As a concatenation of two rigid body-movements is again a rigid body movement, the product on \( SE(3) \) is given by (6). The group \( SE(3) \) is a semi-direct product of the translation group \( \mathbb{R}^3 \) and the rotation group \( SO(3) \), since it uses an isomorphism \( R \mapsto (x \mapsto Rx) \) from the rotation group onto the automorphisms on \( \mathbb{R}^3 \). Therefore we write \( \mathbb{R}^3 \times SO(3) \) rather than \( \mathbb{R}^3 \times SO(3) \) which would yield a direct product. The groups \( SE(3) \) and \( SO(3) \) are not commutative. Throughout this article we will use Euler-angle parametrization for \( SO(3) \), i.e. we write every rotation as a product of a rotation.

---

\(^1\)If \( S^2 \) were a Lie-group then its left-invariant vector fields would be non-zero everywhere, contradicting Poincaré’s “hairy ball theorem” (proven by Brouwer in 1912), or more generally the Poincaré-Hopf theorem (the Euler-characteristic of an even dimensional sphere \( S^{2n} \) is 2).

12
around the $z$-axis, a rotation around the $y$-axis and a rotation around the $z$-axis again.

$$R = R_{e_3, \gamma} R_{e_3, \beta} R_{e_3, \alpha}, \quad (12)$$

where all rotations are counter-clockwise. Explicit formulas for matrices $R_{e_3, \gamma}, R_{e_3, \beta}, R_{e_3, \alpha}$, are given in [38, ch.7.3.1]. The advantage of the Euler angle parametrization is that it directly parameterizes $SO(3)/SO(2) \cong S^2$ as well. Here we recall that $SO(3)/SO(2)$ denotes the partition of all left cosets which are equivalence classes $[g] = \{ h \in SO(3) \mid h \sim g \} = g \cdot SO(2)$ under the equivalence relation $g_1 \sim g_2 \iff g_1^{-1} g_2 \in SO(2)$ where we identified $SO(2)$ with rotations around the $z$-axis and we have

$$SO(3)/SO(2) \ni [R_{e_3, \gamma} R_{e_3, \beta}] = \{ R_{e_3, \gamma} R_{e_3, \beta} R_{e_3, \alpha} \mid \alpha \in [0, 2\pi) \} \leftrightarrow n(\beta, \gamma) := (\cos \gamma \sin \beta, \sin \gamma \sin \beta, \cos \beta) = R_{e_3, \gamma} R_{e_3, \beta} R_{e_3, \alpha} e_2 \in S^2. \quad (13)$$

Like all parameterizations of $SO(3)/SO(2)$, the Euler angle parametrization suffers from the problem that there does not exist a global diffeomorphism from a sphere to a plane. In the Euler-angle parametrization the ambiguity arises at the north and south-poles:

$$R_{e_3, \gamma} R_{e_3, \beta} = 0 R_{e_3, \alpha} = R_{e_3, \gamma - \delta} R_{e_3, \beta} = 0 R_{e_3, \alpha + \delta}, \quad \text{and} \quad R_{e_3, \gamma} R_{e_3, \beta} = 0 R_{e_3, \alpha} = R_{e_3, \gamma + \delta} R_{e_3, \beta} = 0 R_{e_3, \alpha + \delta}, \quad \text{for all} \ \delta \in [0, 2\pi). \quad (14)$$

Consequently, we occasionally need a second chart to cover $SO(3)$:

$$R = R_{e_3, \gamma} R_{e_3, \beta} R_{e_3, \alpha}, \quad (15)$$

which again implicitly parameterizes $SO(3)/SO(2) \cong S^2$ using different ball-coordinates $\hat{\beta} \in [-\pi, \pi), \hat{\gamma} \in (-\frac{\pi}{2}, \frac{\pi}{2})$,

$$\hat{n}(\hat{\beta}, \hat{\gamma}) = R_{e_3, \gamma} R_{e_3, \beta} e_2 = (\sin \hat{\beta}, -\cos \hat{\beta} \sin \hat{\gamma}, \cos \hat{\beta} \cos \hat{\gamma})^T, \quad (16)$$

but which has ambiguities at the intersection of the equator with the $x$-axis, [33].

$$R_{e_3, \gamma} R_{e_3, \beta} = \pm \frac{\pi}{2} R_{e_3, \alpha} \pm \delta R_{e_3, \beta} = \pm \frac{\pi}{2} R_{e_3, \alpha} \pm \delta, \quad \text{for all} \ \delta \in [0, 2\pi), \quad (17)$$

see Figure 7. Away from the intersection of the $z$ and $x$-axis with the sphere one can accomplish conversion between the two charts by solving for for either $(\hat{\alpha}, \hat{\beta}, \hat{\gamma})$ or $(\alpha, \beta, \gamma)$ in $R_{e_3, \gamma} R_{e_3, \beta} = R_{e_3, \gamma} R_{e_3, \beta} R_{e_3, \alpha}$.

Now that we have explained the isomorphism $n = R_{e_3} \in S^2 \leftrightarrow SO(3)/SO(2) \ni [R]$ explicitly in charts, we return to the domain of HARDI images. Considered as a set, this domain equals the space of 3D-positions and orientations $\mathbb{R}^3 \times S^2$. However, in order to stress the fundamental embedding of the HARDI-domain in $SE(3)$ and the thereby induced (quotient) group-structure we write $\mathbb{R}^3 \times S^2$, which is given by the following Lie-group quotient:

$$\mathbb{R}^3 \times S^2 := (\mathbb{R}^3 \times SO(3))/\{[0] \times SO(2)) \}.$$  

Here the equivalence relation on the group of rigid-motions $SE(3) = \mathbb{R}^3 \rtimes SO(3)$ equals

$$(x, R) \sim (x', R') \iff (x, R)^{-1} (x', R') \in \{0\} \times SO(2) \iff x = x' \quad \text{and \ } R^{-1} R' \text{ is a rotation around } z\text{-axis}$$

and set of equivalence classes within $SE(3)$ under this equivalence relation (i.e. left cosets) equals the space of coupled orientations and positions and is denoted by $\mathbb{R}^3 \times S^2$.

### 3 Linear Convolutions on $\mathbb{R}^3 \times S^2$

In this article we will consider convection-diffusion operators on the space of HARDI images. We shall model the space of HARDI images by the space of square integrable functions on the coupled space of positions and orientations, i.e. $L_2(\mathbb{R}^3 \times S^2)$. We will first show that such operators should be left-invariant with respect to the left-action of $SE(3)$ on the space of HARDI images. This left-action of the group $SE(3)$ onto $\mathbb{R}^3 \times S^2$ is given by

$$g \cdot (y, n) = (Ry + x, Rn), \quad g = (x, R) \in SE(3), x, y \in \mathbb{R}^3, n \in S^2, R \in SO(3) \quad (18)$$

and it induces the so-called left-regular action of the same group on the space of HARDI images similar to the left-regular action on 3D-images (for example orientation-marginals of HARDI images):
Figure 7: The two charts which together appropriately parameterize the sphere \( S^2 \equiv SO(3)/SO(2) \) where the rotation-parameters \( \alpha \) and \( \tilde{\alpha} \) are free. The first chart (left-image) is the common Euler-angle parametrization (12), the second chart is given by (15). The first chart has singularities at the north and at the south-pole (inducing ill-defined rotation-parameters \( \alpha \)). The second chart has singularities at \( (\pm 1, 0, 0) \).

**Definition 2** The left-regular actions of \( SE(3) \) onto \( L_2(\mathbb{R}^3 \times S^2) \) respectively \( L_2(\mathbb{R}^3) \) are given by

\[
(L_g)_{(x,n)}U(y,n) = U(g^{-1} \cdot (y,n)) = U(R^{-1}(y-x), R^{-1}n), \quad x, y \in \mathbb{R}^3, n \in S^2, U \in L_2(\mathbb{R}^3 \times S^2), \quad R \in SO(3), x, y \in \mathbb{R}^3, f \in L_2(\mathbb{R}^3).
\]

Intuitively, \( L_g = (x, R) \) represents a rigid motion operator on images, whereas \( L_g = (x, R) \) represents a rigid motion on HARDI images.

Operator on HARDI-images must be left-invariant as the net operator on a HARDI-image should commute with rotations and translations. For detailed motivation see [33], where our motivation is similar as in our framework of invertible orientation scores \([4, 39, 38, 32, 31, 27, 26, 30, 29]\).

**Theorem 1** Let \( \mathcal{K} \) be a bounded operator from \( L_2(\mathbb{R}^3 \times S^2) \) into \( L_\infty(\mathbb{R}^3 \times S^2) \) then there exists an integrable kernel \( k : (\mathbb{R}^3 \times S^2) \times (\mathbb{R}^3 \times S^2) \rightarrow \mathbb{C} \) such that \( \|\mathcal{K}\|^2 = \sup_{(y,n) \in \mathbb{R}^3 \times S^2} \int_{\mathbb{R}^3 \times S^2} |k(y,n ; y', n')| \, dy' \, d\sigma(n') \) and we have

\[
(\mathcal{K}U)(y,n) = \int_{\mathbb{R}^3 \times S^2} k(y,n ; y', n') U(y', n') \, dy' \, d\sigma(n'),
\]

for almost every \((y,n) \in \mathbb{R}^3 \times S^2\) and all \( U \in L_2(\mathbb{R}^3 \times S^2) \). Now \( \mathcal{K}_k := \mathcal{K} \) is left-invariant iff \( k \) is left-invariant, i.e.

\[
\mathcal{L}_g \circ \mathcal{K}_k = \mathcal{K}_k \circ \mathcal{L}_g \leftrightarrow \forall g \in SE(3) \forall y, y' \in \mathbb{R}^3 \forall n, n' \in S^2 : \ k(g \cdot (y,n) ; g \cdot (y',n')) = k(y,n ; y', n'). \quad (20)
\]

Then to each positive left-invariant kernel \( k : \mathbb{R}^3 \times S^2 \times \mathbb{R}^3 \times S^2 \rightarrow \mathbb{R}^+ \) with \( \int_{\mathbb{R}^3} \int_{S^2} k(\mathbf{0}, \mathbf{e}_z ; y,n) \, d\sigma(n) \, dy = 1 \) we can associate a unique probability density \( p : \mathbb{R}^3 \times S^2 \rightarrow \mathbb{R}^+ \) with the invariance property

\[
p(y,n) = p(R_{\epsilon_z, \alpha} \mathbf{y}, R_{\epsilon_z, \alpha} \mathbf{n}), \quad \text{for all } \alpha \in [0, 2\pi),
\]

by means of \( p(y,n) = k(y,n ; \mathbf{0}, \mathbf{e}_z) \). The convolution now reads

\[
\mathcal{K}_k U(y,n) = (p *_{\mathbb{R}^3 \times S^2} U)(y,n) = \int_{\mathbb{R}^3} \int_{S^2} p(R_{\alpha}(y-y'), R_{\alpha}^T n) \, U(y', n') \, d\sigma(n') \, dy',
\]

where \( \sigma \) denotes the surface measure on the sphere and where \( R_{\alpha} \) is any rotation such that \( n' = R_{\alpha} \mathbf{e}_z \).
For details see [33]. By the invariance property (21), the convolution (22) on $\mathbb{R}^3 \times S^2$ may be written as a (full) $SE(3)$-convolution. To this end we extend our positively valued functions $U$ defined on the quotient $\mathbb{R}^3 \times S^2 = (\mathbb{R}^3 \times SO(3))/\{(0) \times SO(2)\}$ to the full Euclidean motion group by means of Eq. (3) which yields
\begin{equation}
\tilde{U}(x, R_{\varepsilon, \gamma} R_{\varepsilon, \beta} R_{\varepsilon, \alpha}) = U(x, n(\beta, \gamma)).
\end{equation}
(23)
in Euler angles. Throughout this article we will use this natural extension to the full group.

**Definition 3** We will call $\tilde{U} : \mathbb{R}^3 \times SO(3) \to \mathbb{R}$, given by Eq. (3), the HARDI-orientation score corresponding to HARDI image $U : \mathbb{R}^3 \times S^2 \to \mathbb{R}$.

**Remark 1** By the construction of a HARDI-orientation score, Eq. (3), it satisfies the following invariance property $U(x, R R_{\varepsilon, \alpha}) = U(x, R)$ for all $x \in \mathbb{R}^3$, $R \in SO(3)$, $\alpha \in [0, 2\pi)$.

An $SE(3)$ convolution [17] of two functions $\tilde{p} : SE(3) \to \mathbb{R}, \tilde{U} : SE(3) \to \mathbb{R}$ is given by:
\begin{equation}
(\tilde{p} *_{SE(3)} \tilde{U})(g) = \int_{SE(3)} \tilde{p}(h^{-1} g) \tilde{U}(h) d\mu_{SE(3)}(h),
\end{equation}
where Haar-measure $d\mu_{SE(3)}(x, R) = dx d\mu_{SO(3)}(R)$ with $d\mu_{SO(3)}(R_{\varepsilon, \gamma} R_{\varepsilon, \beta} R_{\varepsilon, \alpha}) = \sin \beta d\alpha d\beta d\gamma$. It is easily verified that the following identity holds:
\begin{equation}
(\tilde{p} *_{SE(3)} \tilde{U})(x, R) = 2\pi (p *_{\mathbb{R}^3 \times S^2} U)(x, R). \nonumber
\end{equation}

Later on in this article (in Subsection 8.1 and Subsection 8.2) we will relate scale spaces on HARDI data and first order Tikhonov regularization on HARDI data to Markov processes. But in order to provide a road map of how the group-convolutions will appear in the more technical remainder of this article we provide some preliminary explanations on probabilistic interpretation of $\mathbb{R}^3 \times S^2$-convolutions.

### 4 Left-invariant Vector Fields on $SE(3)$ and their Dual Elements

We will use the following basis for the tangent space $T_e(SE(3))$ at the unity element $e = (0, I) \in SE(3)$:
\begin{equation}
A_1 = \partial_x, A_2 = \partial_y, A_3 = \partial_z, A_4 = \partial_\alpha, A_5 = \partial_\beta, A_6 = \partial_\gamma,
\end{equation}
where we stress that at the unity element $(0, R = I)$, we have $\beta = 0$ and here the tangent vectors $\partial_\beta$ and $\partial_\gamma$ are not defined, which requires a description of the tangent vectors on the $SO(3)$-part by means of the second chart.

The tangent space at the unity element is a 6D Lie algebra equipped with Lie bracket
\begin{equation}
[A, B] = \lim_{t \to 0} t^{-2} \left( a(t)b(t)(a(t))^{-1}(b(t))^{-1} - e \right),
\end{equation}
where $t \mapsto a(t)$ resp. $t \mapsto b(t)$ are any smooth curves in $SE(3)$ with $a(0) = b(0) = e$ and $a'(0) = A$ and $b'(0) = B$, for explanation on the formula (26) which holds for general matrix Lie groups, see [28, App.G]. The Lie-brackets of the basis given in Eq. (25) are given by
\begin{equation}
[A_i, A_j] = \sum_{k=1}^{6} c_{ij}^k A_k,
\end{equation}
where the non-zero structure constants for all three isomorphic Lie-algebras are given by
\begin{equation}
-c_{ji}^k = c_{ij}^k = \left\{ \begin{array}{ll}
\text{sgn perm}\{i - 3, j - 3, k - 3\} & \text{if } i, j, k \geq 4, i \neq j \neq k, \\
\text{sgn perm}\{i, j - 3, k\} & \text{if } i, k \leq 3, j \geq 4, i \neq j \neq k.
\end{array} \right.
\end{equation}
More explicitly, we have the following table of Lie-brackets:

\[
([A_i, A_j])_{i=1,...,6} =
\begin{pmatrix}
0 & 0 & 0 & 0 & A_3 & -A_2 \\
0 & 0 & 0 & -A_3 & 0 & A_1 \\
0 & 0 & A_2 & -A_1 & 0 & 0 \\
-A_3 & 0 & A_1 & -A_6 & 0 & A_4 \\
A_2 & -A_1 & 0 & A_5 & -A_4 & 0 \\
A_3 & 0 & A_1 & -A_6 & 0 & A_4 \\
\end{pmatrix},
\]

(i) so for example \(c_{15}^3 = 1, c_{14}^3 = c_{25}^2 = 0, c_{26}^2 = -c_{61}^2 = -1\). The corresponding left-invariant vector fields \(\{A_i\}_{i=1}^6\) are obtained by the push-forward of the left-multiplication \(L_g h = gh\) by \(A_i|_g \phi = (L_g)_* A_i \phi = A_i (\phi \circ L_g)\) (for all smooth \(\phi : \Omega_g \to \mathbb{R}\) which are locally defined on some neighborhood \(\Omega_g\) of \(g\)) and they can be obtained by the derivative of the right-regular representation:

\[
A_i|_g \phi = (dR(A_i) \phi)(g) = \lim_{t \to 0} \frac{\phi(g e^{tA_i}) - \phi(g)}{t}, \quad \text{with } R_g \phi(\delta) = \phi(hg).
\]

Expressed in the first coordinate chart, Eq. (12), this renders for the left-invariant derivatives at position \(g = (x, y, z, R_{e_x, \gamma} R_{e_y, \beta} R_{e_z, \alpha}) \in SE(3)\) (see also [17, Section 9.10])

\[
\begin{align*}
A_1 &= -\cos \alpha \cos \beta \cos \gamma - \sin \alpha \sin \gamma & A_4 &= -\cos \alpha \cos \beta \cos \gamma - \sin \alpha \sin \gamma \\
A_2 &= -\sin \alpha \cos \beta \cos \gamma + \cos \alpha \sin \gamma & A_5 &= \cos \alpha \sin \beta \sin \gamma + \cos \alpha \cos \beta \sin \gamma \\
A_3 &= \sin \beta \cos \gamma & A_6 &= \sin \beta \cos \gamma,
\end{align*}
\]

for \(\beta \neq 0\) and \(\beta \neq \pi\). The explicit formulae of the left-invariant vector fields in the second chart, Eq. (15), are:

\[
\begin{align*}
A_1 &= \cos \tilde{\alpha} \cos \tilde{\beta} \cos \tilde{\gamma} + (\cos \gamma \sin \tilde{\alpha} + \cos \tilde{\alpha} \sin \tilde{\beta} \sin \gamma) \partial_x + (\sin \alpha \cos \gamma - \cos \alpha \sin \beta \sin \gamma) \partial_y - \cos \alpha \sin \beta \partial_z, \\
A_2 &= -\sin \alpha \cos \beta \cos \gamma + (\cos \alpha \sin \gamma + \sin \alpha \sin \beta \cos \gamma) \partial_x + (\sin \alpha \cos \gamma - \cos \alpha \sin \beta \sin \gamma) \partial_y + \cos \alpha \sin \beta \partial_z, \\
A_3 &= \sin \beta \cos \gamma - \cos \alpha \sin \beta \sin \gamma + \cos \alpha \cos \beta \sin \gamma \partial_x + (\sin \alpha \sin \beta \cos \gamma + \cos \alpha \sin \beta \sin \gamma) \partial_y - \cos \alpha \sin \beta \partial_z, \\
A_4 &= -\cos \tilde{\alpha} \tan \tilde{\beta} \partial_x + \sin \tilde{\alpha} \partial_y + \frac{\sin \tilde{\alpha}}{\cos \tilde{\beta}} \partial_z, \\
A_5 &= \sin \tilde{\beta} \cos \tilde{\gamma} - \sin \tilde{\alpha} \sin \tilde{\beta} \sin \tilde{\gamma} \partial_x + \cos \tilde{\alpha} \sin \tilde{\beta} \cos \tilde{\gamma} \partial_y + \cos \tilde{\alpha} \cos \tilde{\beta} \cos \tilde{\gamma} \partial_z, \\
A_6 &= \partial_z.
\end{align*}
\]

for \(\tilde{\alpha} \neq \frac{\pi}{2}\) and \(\tilde{\beta} \neq -\frac{\pi}{2}\). Note that \(dR\) is a Lie-algebra isomorphism, i.e.

\[
[A_1, A_j] = \sum_{k=1}^6 c_{ij}^k A_k \iff [dR(A_1), dR(A_j)] = \sum_{k=1}^6 c_{ij}^k dR(A_k) \iff [A_i, A_j] = A_i A_j - A_j A_i = \sum_{k=1}^6 c_{ij}^k A_k.
\]

These vector fields form a local moving coordinate frame of reference on \(SE(3)\). The corresponding dual frame \(\{dA^1, \ldots, dA^6\} \in (T(SE(3)))^*\) is defined by duality. A brief computation yields:

\[
\begin{pmatrix}
\frac{dA^1}{dx} \\
\frac{dA^2}{dy} \\
\frac{dA^3}{dz} \\
\frac{dA^4}{do} \\
\frac{dA^5}{d\sin \alpha} \\
\frac{dA^6}{d\gamma}
\end{pmatrix} =
\begin{pmatrix}
(R_{e_x, \gamma} R_{e_y, \beta} R_{e_z, \alpha})^T & 0 \\
0 & M_{\beta, \alpha}
\end{pmatrix}
\begin{pmatrix}
\frac{dx}{d\alpha} \\
\frac{dy}{d\beta} \\
\frac{dz}{d\gamma}
\end{pmatrix} =
\begin{pmatrix}
(R_{e_x, \gamma} R_{e_y, \beta} R_{e_z, \alpha})^T & 0 \\
0 & M_{\beta, \alpha}
\end{pmatrix}
\begin{pmatrix}
\frac{dx}{d\alpha} \\
\frac{dy}{d\beta} \\
\frac{dz}{d\gamma}
\end{pmatrix} =
\begin{pmatrix}
(R_{e_x, \gamma} R_{e_y, \beta} R_{e_z, \alpha})^T & 0 \\
0 & M_{\beta, \alpha}
\end{pmatrix}
\begin{pmatrix}
\frac{dx}{d\alpha} \\
\frac{dy}{d\beta} \\
\frac{dz}{d\gamma}
\end{pmatrix}
\]

where the \(3 \times 3\)-zero matrix is denoted by \(0\) and where the \(3 \times 3\)-matrices \(M_{\beta, \alpha}\), \(\tilde{M}_{\beta, \alpha}\) are given by

\[
M_{\beta, \alpha} =
\begin{pmatrix}
0 & \cos \alpha \sin \beta \\
\cos \alpha & \sin \beta \\
1 & 0
\end{pmatrix}, \quad 
\tilde{M}_{\beta, \alpha} =
\begin{pmatrix}
-\cos \tilde{\alpha} \tan \tilde{\beta} & \sin \tilde{\alpha} & \frac{\sin \tilde{\alpha}}{\cos \tilde{\beta}} \\
\sin \tilde{\alpha} \tan \tilde{\beta} & \cos \tilde{\alpha} & -\frac{\sin \tilde{\alpha}}{\cos \tilde{\beta}} \\
1 & 0 & 0
\end{pmatrix}^{-T}.
\]

Finally, we note that by linearity the \(i\)-th dual vector filters out the \(i\)-th component of a vector field \(\sum_{j=1}^6 v^j A_j\):

\[
\langle dA^i, \sum_{j=1}^6 v^j A_j \rangle = v^i, \quad \text{for all } i = 1, \ldots, 6.
\]
Remark 2 In our numerical schemes, we do not use the formulas (31) and (32) for the left-invariant vector fields as we want to avoid sampling around the inevitable singularities that arise with the the coordinate charts, given by Eq. (12) and (15), of S². Instead in our numerics we use the approach that will be described in Section 12. However, we shall use formulas (31) and (32) frequently in our analysis and derivation of Green’s functions of left-invariant diffusions and left-invariant Hamilton-Jacobi equations on R³ x S². These left-invariant diffusions and left-invariant erosions are similar to diffusions and erosions on R⁵, we “only” have to replace the fixed left-invariant vector fields \{\partial_{x_1}, \ldots, \partial_{x_5}\} by the left-invariant vector fields \{\mathcal{A}_1|_y, \ldots, \mathcal{A}_5|_y\} which serve as a moving frame of reference (along fiber fragments) in R³ x S² = SE(3)/\{0\} x SO(2)). For an a priori geometric intuition behind our left-invariant erosions and diffusions expressed in the left-invariant vector fields see Figure 6.

5 Morphological Convolutions on R³ x S²

Dilations on the joint space of positions and orientations R³ x S² are obtained by replacing the (+, ·)-algebra by the (max, +)-algebra in the R³ x S²-convolutions (22)

\[(k \oplus_{R^3 \times S^2} U)(y, n) = \sup_{(y', n') \in R^3 \times S^2} \left[ k(R^T_{n'}(y - y'), R^T_{n'}n) + U(y', n') \right] \]

(34)

where k denotes a morphological kernel. If this morphological kernel is induced by a semigroup (or evolution) then we write kₜ for the kernel at time t. Our aim is to derive suitable morphology kernels such that

\[k_t \oplus_{R^3 \times S^2} k_s = k_{s+t}, \text{ for all } s, t > 0,\]

where t \mapsto kₜ(y, n) describes the growth of balls in R³ x S², i.e. t \mapsto kₜ(y, n) is the unique viscosity solution, see [19] and Appendix B, of

\[\begin{cases}
\frac{\partial W}{\partial t}(y, n, t) = \frac{1}{2} G_{y,n}^{-1} \left( dW(\cdot, t)|_{y,n}, dW(\cdot, t)|_{y,n} \right) \\
W(y, n, 0) = -\delta^{C}\end{cases}\]

(35)

with the inverse G⁻¹ of the metric tensor restricted to the sub-Riemannian manifold (SE(3), dA¹, dA⁶)

\[G = \frac{1}{D^{11}} (A_1 \otimes A_1 + A_2 \otimes A_2) + \frac{1}{D^{44}} (A_4 \otimes A_4 + A_5 \otimes A_5),\]

(36)

given by

\[G^{-1} = D^{11} (A_1 \otimes A_1 + A_2 \otimes A_2) + D^{44} (A_4 \otimes A_4 + A_5 \otimes A_5).\]

Both G and its inverse are well-defined on the cosets R³ x S² = (R³ x SO(3))/\{0\} x SO(2)), cf. Appendix E. Furthermore, in Eq. (35) we have used the morphological delta distribution \(\delta^{C}(y, n) = +\infty\) if \((y, n) \neq (0, e_z)\) and 0 else, where we note that

\[\lim_{t \downarrow 0} k_t \oplus_{R^3 \times S^2} U = (-\delta^C) \oplus_{R^3 \times S^2} U = U\]

uniformly on R³ x S². Furthermore, we have used the left-invariant gradient which is the co-vector field

\[dU(y, n) = \sum_{i=1}^{6} (A_i(U))(y, n) \ dA^i|_{(y,n)}, \ y, n \in R^3 \times S^2,\]

(37)

which we occasionally represent by a row vector given by

\[\nabla U(y, n) = (A_1 U(y, n), \ldots, A_5 U(y, n), 0).\]

(38)

The dilatation equation (35) now becomes

\[\begin{cases}
\frac{\partial W}{\partial t}(y, n, t) = \frac{1}{2} (D^{11}((A_1 W(y, n, t))^2 + (A_2 W(y, n, t))^2) + D^{44}((A_4 W(y, n, t))^2 + (A_5 W(y, n, t))^2)) \\
W(y, n, 0) = -\delta^{C}(y, n).
\end{cases}\]
Now we can consider either a positive definite metric (the case of dilations), or we can consider a negative definite metric (the case of erosions). In the non-adaptive case this means; either we consider the $g_{ii} = \frac{1}{\sigma_i^2} > 0$ or we choose them $g_{ii} = -\frac{1}{\sigma_i^2} < 0$. Note that the erosion kernel follows from the dilation kernel by negation $k_t \mapsto -k_t$. Dilation kernels are negative and erosion kernels are positive and therefore we write

$$k_t^+ := -k_t \geq 0 \quad \text{and} \quad k_t^- := k_t \leq 0.$$  

for the erosion kernels. Erosions on $\mathbb{R}^3 \times S^2$ are given by:

$$(k_t^+ \ominus_{\mathbb{R}^3 \times S^2} U)(y, n) = \inf_{(y', n') \in \mathbb{R}^3 \times S^2} \left[ U(y', n') + k_t^+(R^T_n (y - y'), R^T_n n) \right]. \tag{39}$$

We distinguish between three types of erosions/dilations on $\mathbb{R}^3 \times S^2$

1. Angular erosion/dilation (i.e. erosion on glyphs): In case $g_{11} = g_{33} = 0$ and $g_{44} < 0$ the erosion kernels are given by

$$k_t^{+, g_{11}=0, g_{44}}(y, n) = \begin{cases} \infty & \text{if } y \neq 0 \\ k_t^{+, g_{11}=0, g_{44}}(0, n) & \text{else} \end{cases}$$

such that the angular erosions are given by

$$\left(k_t^{+, g_{11}=0, g_{44}} \ominus_{\mathbb{R}^3 \times S^2} U\right)(y, n) = \left(k_t^{+, g_{11}=0, g_{44}}(0, \cdot) \ominus_{S^2} U(y, \cdot)\right)(n)$$

$$= \inf_{n' \in S^2} \left[ k_t^{+, g_{11}=0, g_{44}}(0, R^T_n (n')) + U(y', n') \right] \tag{40}$$

whereas the angular dilations $g_{44} > 0$ are given by

$$\left(k_t^{-, g_{11}=g_{33}=0, g_{44}} \oplus_{\mathbb{R}^3 \times S^2} U\right)(y, n) = \left(k_t^{-, g_{11}=g_{33}=0, g_{44}}(0, \cdot) \oplus_{S^2} U(y, \cdot)\right)(n)$$

$$= \sup_{n' \in S^2} \left[ k_t^{-, g_{11}=g_{33}=0, g_{44}}(0, R^T_n (n')) + U(y', n') \right] \tag{41}$$

2. Spatial erosion/dilation (i.e. the same spatial erosion for all orientations): In case $g_{11} g_{33} \neq 0$, $g_{11} \leq 0$, $g_{33} \leq 0$ and $g_{44} = 0$ the erosion kernels are given by

$$k_t^{+, g_{11}=g_{33} g_{44}=0}(y, n) = \begin{cases} \infty & \text{if } n \neq e_z \\ k_t^{+, g_{11}=g_{33} g_{44}=0}(y, e_z) & \text{else} \end{cases}$$

such that the spatial erosions are given by

$$\left(k_t^{+, g_{11}=g_{33} g_{44}=0} \ominus_{\mathbb{R}^3 \times S^2} U\right)(y, n) = \left(k_t^{+, g_{11}=g_{33} g_{44}=0}(\cdot, e_z) \ominus_{\mathbb{R}^3} U(\cdot, n)\right)(y)$$

whereas the spatial dilations $g_{11}, g_{33} \geq 0$, $g_{11} g_{33} > 0$ are given by

$$\left(k_t^{-, g_{11}=g_{33} g_{44}=0} \oplus_{\mathbb{R}^3 \times S^2} U\right)(y, n) = \left(k_t^{-, g_{11}=g_{33} g_{44}=0}(\cdot, e_z) \oplus_{\mathbb{R}^3} U(\cdot, n)\right)(y).$$

3. Simultaneous spatial and angular erosion/dilations (i.e. erosions and dilations along fibers). The case $g_{44} \neq 0$ and $g_{11} \neq 0$ or $g_{33} \neq 0$.

Similar to our previous work on $\mathbb{R}^3 \times S^2$-diffusion [25] the third case is the most interesting one, simply because one would like to erode orthogonal to the fibers such that both the angular distribution and the spatial distribution of the a priori probability density $U : \mathbb{R}^3 \times S^2 \rightarrow \mathbb{R}^+$ are sharpened. See Figure 8.
Figure 8: Top row: output angular erosion on a single glyph with crossings for several parameter settings. Middle row: input and output simultaneous spatial and angular erosion (i.e. $\mathbb{R}^3 \times S^2$-erosion), where angular erosion dominates $t = 3$, $D^{44} = 0.6$, $D^{33} = 0.3$. Bottom row: input and output $\mathbb{R}^3 \times S^2$-erosion, where angular spatial erosion dominates $t = 2$, $D^{44} = 0.1$, $D^{33} = 0.3$. 
6 Left-Invariant Diffusions on $SE(3) = \mathbb{R}^3 \rtimes SO(3)$ and $\mathbb{R}^3 \rtimes S^2$

In order to apply our general theory on diffusions on Lie groups, [26], to suitable (convection-)diffusions on HARDI images, we first extend all functions $U : \mathbb{R}^3 \rtimes S^2 \to \mathbb{R}^+$ to functions $\tilde{U} : \mathbb{R}^3 \rtimes SO(3) \to \mathbb{R}^+$ in the natural way, by means of (3).

Then we follow our general construction of scale space representations $\tilde{W}$ of functions $\tilde{U}$ (could be an image, or a score/wavelet transform of an image) defined on Lie groups, [26], where we consider the special case $G = SE(3)$:

\[
\begin{align*}
\partial_t \tilde{W}(g, t) &= Q^{D, a}(A_1, A_2, \ldots, A_6) \tilde{W}(g, t), \\
\lim_{t \to 0} \tilde{W}(g, t) &= \tilde{U}(g).
\end{align*}
\]

which is generated by a quadratic form on the left-invariant vector fields:

\[
Q^{D, a}(\nabla) := Q^{D, a}(A_1, A_2, \ldots, A_n) = \sum_{i=1}^{6} -a_i A_i + \sum_{j=1}^{6} A_i D^{ij} A_j
\tag{42}
\]

Now the Hörmander requirement, [47], on the symmetric $D = [D^{ij}] \in \mathbb{R}^{6 \times 6}$, $D \geq 0$ and $a$, which guarantees smooth non-singular scale spaces, for $SE(3)$ tells us that $D$ need not be strictly positive definite. The Hörmander requirement is that all included generators together with their commutators should span the full tangent space. To this end for diagonal $D$ one should consider the set

$S = \{ i \in \{1, \ldots, 6\} \mid D^{ii} \neq 0 \lor a_i \neq 0 \}$,

now if for example 1 is not in here then 3 and 5 must be in $S$, or if 4 is not in $S$ then 5 and 6 should be in $S$. If the Hörmander condition is satisfied the solutions of the linear diffusions (i.e. $D, a$ are constant) are given by $SE(3)$-convolution with a smooth probability kernel $p_{t}^{D, a} : SE(3) \to \mathbb{R}^{+}$ such that

\[
\begin{align*}
\tilde{W}(g, t) &= (p_{t}^{D, a} \ast_{SE(3)} \tilde{U})(g) = \int_{SE(3)} p_{t}^{D, a}(h^{-1}g)\tilde{U}(h) d\mu_{SE(3)}(h),
\end{align*}
\]

\[
\lim_{t \to 0} p_{t}^{D, a} \ast_{SE(3)} \tilde{U} = \tilde{U},
\]

with $p_{t}^{D, a} > 0$ and $\int_{SE(3)} p_{t}^{D, a}(g) d\mu_{SE(3)}(g) = 1$.

where the limit is taken in $L_{2}(SE(3))$-sense. On HARDI images whose domain equals the homogeneous space $\mathbb{R}^3 \rtimes S^2$ one has the following scale space representations:

\[
\begin{align*}
\partial_t W(y, n, t) &= Q^{D(U), a(U)}(A_1, A_2, \ldots, A_3) W(y, n, t), \\
W(y, n, 0) &= U(y, n).
\end{align*}
\tag{44}
\]

with $Q^{D(U), a(U)}(A_1, A_2, \ldots, A_n) = \sum_{i=1}^{6} \left( a_i A_i + \sum_{j=1}^{6} A_i D^{ij} (U) A_j \right)$, where from now on we assume that $D(U)$ and $a(U)$ satisfy

\[
a(\tilde{U})(gh) = Z_{\alpha}^{T} (a)(g) \text{ and } D(\tilde{U})(gh) = Z_{\alpha} D(\tilde{U})(g) Z_{\alpha}^{T}.
\tag{45}
\]

for all $g \in SE(3)$ and all $h = (0, R_{e_{z}, \alpha}) \in \{0\} \times SO(2)$ and where

\[
Z_{\alpha} = \begin{pmatrix}
\cos \alpha & -\sin \alpha & 0 & 0 & 0 & 0 \\
\sin \alpha & \cos \alpha & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & \cos \alpha & -\sin \alpha & 0 \\
0 & 0 & 0 & \sin \alpha & \cos \alpha & 0 \\
0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}
= R_{e_{z}, \alpha} \oplus R_{e_{z}, \alpha}, Z_{\alpha} \in SO(6), R_{e_{z}, \alpha} \in SO(3).
\tag{46}
\]

Recall the grey tangent planes in Figure 6 where we must require isotropy due to our embedding of $\mathbb{R}^3 \rtimes S^2$ in $SE(3)$, cf. [33, ch:4].
In the linear case the solutions of (44) are given by the following kernel operators on $\mathbb{R}^3 \times S^2$:

$$
W(y, n, t) = \left( \frac{1}{2\pi} \int_0^\infty \mathcal{F}^{-1} \mathcal{H} \cdot \mathcal{F} U \right)(y, n)
$$

$$
= \int \int \int \frac{1}{2\pi} \mathcal{F}^{-1} \mathcal{H} \cdot \mathcal{F} U((Re_{\gamma} \ast Re_{\beta} \ast T)(y - y'), (Re_{\gamma} \ast Re_{\beta} \ast T)n)) U(y', n(\beta', \gamma')) \, dy' \, d\sigma(n(\beta', \gamma')),
$$

where the surface measure on the sphere is given by $d\sigma(n(\beta', \gamma')) = \sin(\beta') \, d\gamma' \, d\beta' \equiv d\sigma(\tilde{\beta}, \tilde{\gamma}) = |\cos(\tilde{\beta})| \, d\tilde{\beta} \, d\tilde{\gamma}$. Now in particular in the linear case, since $(\mathbb{R}^3, I)$ and $(0, SO(3))$ are subgroups of $SE(3)$, we obtain the Laplace-Beltrami operators on these subgroups by means of:

$$
\Delta_{S^2} = Q = \text{diag}(0, 0, 1, 1, 1, 1), a = 0
$$

$$
\Delta_{\mathbb{R}^3} = Q = \text{diag}(1, 1, 1, 0, 0, 0), a = 0
$$

One wants to include line-models which exploit a natural coupling between position and orientation. Such a coupling is naturally included in a smooth way as long as the Hormander’s condition is satisfied. Therefore we will consider more elaborate simple left-invariant convection, diffusions on $SE(3)$ with natural coupling between position and orientation. To explain what we mean with natural coupling we shall need the next definitions.

**Definition 4** A curve $\gamma : \mathbb{R}^+ \rightarrow \mathbb{R}^3 \times S^2$ given by $s \mapsto \gamma(s) = (y(s), n(s))$ is called horizontal if $n(s) \equiv ||\dot{y}(s)||^{-1}\dot{y}(s)$. A tangent vector to a horizontal curve is called a horizontal tangent vector. A vector field $A$ on $\mathbb{R}^3 \times S^2$ is horizontal if for all $(y, n) \in \mathbb{R}^3 \times S^2$ the tangent vector $A(y, n)$ is horizontal. The horizontal part $H_\gamma$ of each tangent space is the vector-subspace of $T_y(SE(3))$ consisting of horizontal vector fields. Horizontal diffusion is diffusion which only takes place along horizontal curves.

It is not difficult to see that the horizontal part $H_\gamma$ of each tangent space $T_y(SE(3))$ is spanned by $\{A_3, A_4, A_5\}$. So all horizontal left-invariant convection diffusions are given by Eq. (44) where in the linear case one must set $a_1 = a_2 = a_6 = 0, D_{j2} = D_{2j} = D_{1j} = D_{j1} = D_{j6} = D_{6j} = 0$ for all $j = 1, 2, \ldots, 6$. Now on a commutative group like $\mathbb{R}^6$ with commutative Lie-algebra $\{\partial_{x_1}, \ldots, \partial_{x_6}\}$ omitting 3-directions (say $\partial_{x_1}, \partial_{x_2}, \partial_{x_3}$) from each tangent space in the diffusion would yield no smoothing along the global $x_1, x_2, x_4$-axes. In $SE(3)$ it is different since the commutators take care of indirect smoothing in the omitted directions $\{A_1, A_2, A_6\}$, since

$$
$$

Consider for example the $SE(3)$-analogues of the Forward-Kolmogorov (or Fokker-Planck) equations of the direction process for contour-completion and the stochastic process for contour enhancement which we considered in our previous work, [29], on $SE(2)$. Here we first provide the resulting PDEs and explain the underlying stochastic processes later in subsection 8.1. The Fokker-Planck equation for (horizontal) contour completion on $SE(3)$ is given by

$$
\left\{ \begin{array}{ll}
\partial_t W(y, n, t) &= (-A_3 + D((A_4)^2 + (A_5)^2)) W(y, n, t) = (-A_3 + D \Delta_{S^2}) W(y, n, t), D = 1/2 \sigma^2 > 0, \\
\lim_{t \downarrow 0} W(y, n, t) &= U(y, n).
\end{array} \right.
$$

where we note that $(A_6)^2(W(y, n(\beta, \gamma), s)) = 0$. This equation arises from Eq. (44) by setting $D_{44} = D_{55} = D$ and $a_3 = 1$ and all other parameters to zero. The Fokker-Planck equation for (horizontal) contour enhancement is

$$
\left\{ \begin{array}{ll}
\partial_t W(y, n, t) &= (D^{33}(A_3)^2 + D^{44}((A_4)^2 + (A_5)^2)) W(y, n, t) = (D^{33}(A_3)^2 + D \Delta_{S^2}) W(y, n, t), \\
\lim_{t \downarrow 0} W(y, n, t) &= U(y, n).
\end{array} \right.
$$

The solutions of the left-invariant diffusions on $\mathbb{R}^3 \times S^2$ given by (44) (with in particular (48) and (49)) are again given by convolution product (47) with a probability kernel $p_t^\mathcal{D} \mathcal{H}$ on $\mathbb{R}^3 \times S^2$. For a visualization of these probability kernels, see Figure 10.
7 Left-invariant Hamilton-Jacobi Equations on $\mathbb{R}^3 \rtimes S^2$

The unique viscosity solutions of

\[
\begin{aligned}
\left\{ \begin{array}{l}
\frac{\partial W}{\partial t}(\gamma, n, t) = \frac{1}{2\eta} G^{-1}_{(\gamma, n)} \left( dW(\cdot, t)|_{y, n}, dW(\cdot, t)|_{y, n} \right) \\
W(\gamma, n, 0) = U(\gamma, n),
\end{array} \right.
\end{aligned}
\]

(50)

where $\eta \geq \frac{1}{2}$, are given by dilation, Eq. (34), with the morphological Green’s function $k_{t}^{D^{11}, D^{44}, n,-} : \mathbb{R}^3 \rtimes S^2 \rightarrow \mathbb{R}^-$

\[
W(\gamma, n, t) = (k_{t}^{D^{11}, D^{44}, n,-} \circ U)(\gamma, n),
\]

(51)

whereas the unique viscosity solutions of

\[
\begin{aligned}
\left\{ \begin{array}{l}
\frac{\partial W}{\partial t}(\gamma, n, t) = -\frac{1}{2\eta} G^{-1}_{(\gamma, n)} \left( dW(\cdot, t)|_{y, n}, dW(\cdot, t)|_{y, n} \right) \\
W(\gamma, n, 0) = U(\gamma, n),
\end{array} \right.
\end{aligned}
\]

(52)

are given by erosion, Eq. (39), with the morphological Green’s function $k_{t}^{D^{11}, D^{44}, n,+} : \mathbb{R}^3 \rtimes S^2 \rightarrow \mathbb{R}^+$

\[
W(\gamma, n, t) = (k_{t}^{D^{11}, D^{44}, n,+} \circ U)(\gamma, n),
\]

(53)

This is formally shown in Appendix B, Theorem 4. The exact morphological Green’s functions are given by (where we recall (10))

\[
-k_{t}^{D^{11}, D^{44}, n,-}(\gamma, n) = k_{t}^{D^{11}, D^{44}, n,+}(\gamma, n) := \inf_{\gamma(0) = (0, t \in \mathbb{R}^3)} \int_{0}^{t} \mathcal{L}_{\eta}(\gamma(p), \dot{\gamma}(p)) \, dp,
\]

(54)

with Lagrangian

\[
\mathcal{L}_{\eta}(\gamma(p), \dot{\gamma}(p)) := \frac{2\eta - 1}{2\eta} \left( \frac{1}{D^{11}}((\dot{\gamma}^{1}(p))^{2} + (\dot{\gamma}^{2}(p))^{2}) + \frac{1}{D^{44}}((\dot{\gamma}^{3}(p))^{2} + (\dot{\gamma}^{4}(p))^{2}) \right) \frac{2}{\eta} \tau^{-\eta}
\]

(55)

where we applied short notation $\dot{\gamma}^{i}(p) = \langle dA^{i}|_{\gamma(p)}, \dot{\gamma}(p) \rangle$ and with $\mathbb{R}^3 \rtimes S^2$-“erosion arclength” given by

\[
p(\tau) = \int_{0}^{\tau} \sqrt{G_{\gamma(\tau)}(\gamma(\tau), \dot{\gamma}(\tau))} \, d\tau = \int_{0}^{\tau} \sqrt{\sum_{i \in \{1,2,4,5\}} \frac{1}{D^{11}}|\langle dA^{1}|_{\gamma(\tau)}, \dot{\gamma}(\tau) \rangle|^{2} \, d\tau.
\]

(56)

As motivated in Appendix B, we use the following asymptotical analytical formula for the Green’s function

\[
k_{t}^{D^{11}, D^{44}, n,+}(\gamma, n) \equiv \pm \frac{2\eta - 1}{2\eta} C t^{-\frac{2}{\eta}} \left( \sum_{i=1}^{6} \frac{\tilde{c}^{i}_{\gamma, \tilde{\alpha} = 0, \tilde{\beta}, \tilde{\gamma}}}{D^{i}} \right)^{\frac{2}{\eta}}
\]

(56)

for sufficiently small time $t > 0$, where $C \geq 1$ is a constant that we usually set equal to 1 and where the constants $\tilde{c}^{i}_{\gamma, \tilde{\alpha} = 0, \tilde{\beta}, \tilde{\gamma}}$, $i = 1, \ldots, 6$, are components of the logarithm

\[
\sum_{i=1}^{6} \frac{\tilde{c}^{i}_{\gamma, \tilde{\alpha} = 0, \tilde{\beta}, \tilde{\gamma}}}{D^{i}} A_{i} = \log_{SE(3)}(y, R_{e}, \gamma R_{e}, \tilde{\beta}),
\]

(56)

that we shall derive in Section 9.1, Eq. (75).

Apparently, by Eq. (54) the morphological kernel describes the growth of "erosion balls" in $\mathbb{R}^3 \rtimes S^2$. In Appendix B we show that these erosion balls are locally equivalent to a weighted modulus on the Lie-algebra of $SE(3)$, which explains our asymptotical formula (56). This gives us a simple analytic approximation formula for balls in $\mathbb{R}^3 \rtimes S^2$, where we do not need/use the minimizing curves (i.e. geodesics) in (54).
Figure 9: From left to right, input glyph at say \( y = 0 \). Sample points where \( \Delta_{LB}U(0, n) < 0 \) resp. \( \geq 0 \) are respectively indicated in red and blue. Linearly eroded glyph \((D^{44} = 0.4, t = 0.5, \eta = 1, \Delta t = 0.01)\), adaptive eroded glyph \((D^{44} = 0.4, t = 0.5, \eta = 1, \phi(x) = D^{44}x^\frac{1}{2})\).

**Remark 3** In Appendix G we provide the system of Pfaffian equations for geodesics on the sub-Riemannian manifold \((SE(3), dA^1, dA^2, dA^6)\) as a first step to generalize our results on \(SE(2) = \mathbb{R}^2 \rtimes S^1\) in [30, App. A], where we generalize our results on \(SE(2) = \mathbb{R}^2 \rtimes S^1\) in [30, App. A] to \((SE(3)\). In order to compute the geodesics on the sub-Riemannian manifold \((SE(3), dA^3, dA^6)\) (used in the erosions Eq. 52) a similar approach can be followed.

### 7.1 Data adaptive angular erosion and dilation

In the erosion evolution (52) one can include adaptivity by making \(D^{44}\) depend on the local Laplace-Beltrami-operator

\[
D^{44}(U)(y, n) = \phi(\Delta_{LB}U(y, n) - c).
\]

with \(\phi\) a non-decreasing, odd function and \(\inf_{n \in S^2, y \in \mathbb{R}^3} \Delta_{LB}U(y, n) < c < \sup_{n \in S^2, y \in \mathbb{R}^3} \Delta_{LB}U(y, n)\). The intuitive idea here is to dilate on points on a glyph \(x + \mu\{U(x, x)n \mid n \in S^2\}\) where the Laplace-Beltrami operator is negative (usually around spherical maxima) and to erode on at locations on the glyph where the Laplace-Beltrami operator is positive. Parameter \(c > 0\) tunes the boundary on the glyph where the switch between erosion and dilation takes place, See Figure 9 where we have set \(\phi(x) = D^{44}x^\frac{1}{2}\) while varying \(c\).

### 8 Probability Theory on \(\mathbb{R}^3 \ltimes S^2\)

#### 8.1 Brownian Motions on \(SE(3) = \mathbb{R}^3 \ltimes SO(3)\) and on \(\mathbb{R}^3 \ltimes S^2\)

Next we formulate a left-invariant discrete Brownian motion on \(SE(3)\) (expressed in the moving frame of reference). The left-invariant vector fields \(\{A_1, \ldots, A_6\}\) form a moving frame of reference to the group. Here we note that there are two ways of considering vector fields. Either one considers them as differential operators on smooth locally defined functions, or one considers them as tangent vectors to equivalent classes of curves. These two viewpoints are equivalent, for formal proof see [7, Prop. 2.4]. Throughout this article we mainly use the first way of considering vector
yields the transition probability \( D_{\text{in}}(58) \) are fields, but in this section we prefer to use the second way. We will write \( R \) details see [4, app.A] where one should consistently replace the left-invariant vector fields of \( R \) equations (44) on \( \mathbb{R} \) In particular we have now formulated the contour-enhancement in \( \mathbb{R} \) vector fields on \( \mathbb{R} \) we identified \( SO(3) \) with a ball with radius \( 2\pi \) whose outer-sphere is identified with the origin, using Euler angles \( R_{e_\alpha} R_{e_\beta} R_{e_\gamma} \leftrightarrow \alpha n(\beta, \gamma) \in B_{\theta=2\pi} \). Next we formulate left-invariant discrete random walks on \( SE(3) \) expressed in the moving frame of reference \( \{ e_i \}_{i=1}^6 \) given by (31) and (112):

\[
(Y_{n+1}, N_{n+1}) = (Y_n, N_n) + \Delta s \sum_{i=1}^5 a_i e_{i|Y_n, N_n} + \sqrt{\Delta s} \sum_{i=1}^5 \varepsilon_{i,n+1} \sum_{j=1}^5 \sigma_{ji} e_{j|Y_n, N_n} \quad \text{for all } n = 0, \ldots, N - 1,
\]

\[
(Y_0, n_0) \sim U^{D},
\]

with random variable \( (Y_0, n_0) \) is distributed by \( U^{D} \), where \( U^{D} \) are the discretely sampled HARDI data (equidistant sampling in position and second order tessellation of the sphere) and where the random variables \( (Y_n, N_n) \) are recursively determined using the independently normally distributed random variables \( \{ \varepsilon_{i,n+1} \}_{i=1}^{n=1, \ldots, N-1}, \varepsilon_{i,n+1} \sim \mathcal{N}(0, 1) \) and where the stepsize equals \( \Delta s = \frac{\pi}{\sqrt{2}} \) and where \( \mathbf{a} := \sum_{i=1}^5 a_i e_i \) denotes an apriori spatial velocity vector having constant coefficients \( a_i \) with respect to the moving frame of reference \( \{ e_i \}_{i=1}^6 \) (just like in (43)). Now if we apply recursion and let \( N \to \infty \) we get the following continuous Brownian motion processes on \( SE(3) \):

\[
Y(t) = Y(0) + \frac{t}{0} \left( \sum_{i=1}^3 a_i e_{i|Y(\tau), N(\tau)} + \frac{1}{2} \sigma_{ji} e_{j|Y(\tau), N(\tau)} \right) d\tau,
\]

\[
N(t) = N(0) + \frac{t}{0} \left( \sum_{i=1}^3 a_i e_{i|Y(\tau), N(\tau)} + \frac{1}{2} \sigma_{ji} e_{j|Y(\tau), N(\tau)} \right) d\tau,
\]

with \( \varepsilon_i \sim \mathcal{N}(0, 1) \) and \( (X(0), N(0)) \sim U \) and where \( \sigma = \sqrt{2D} \in \mathbb{R}^{6 \times 6}, \sigma > 0 \). Note that \( d\sqrt{\mathbb{F}} = \frac{1}{\sqrt{\pi}} \sqrt{2} \tau^{-\frac{1}{2}} d\tau \).

Now if we set \( U = \delta_{\mathbf{b}, e_\alpha} \) (i.e. at time zero ) then suitable averaging of infinitely many random walks of this process yields the transition probability \( (y, n) \to p^{D,y}_{t}(y, n) \) which is the Green’s function of the left-invariant evolution equations (44) on \( \mathbb{R}^3 \times S^2 \). In general the PDE’s (44) are the Forward Kolmogorov equation of the general stochastic process (58). This follows by Itō-calculus and in particular Itō’s formula for formulas on a stochastic process, for details see [4, app.A] where one should consistently replace the left-invariant vector fields of \( \mathbb{R}^n \) by the left-invariant vector fields on \( \mathbb{R}^3 \times S^2 \).

In particular we have now formulated the direction process for contour completion in \( \mathbb{R}^3 \times S^2 \) (i.e. non-zero parameters in (58) are \( D^{4} = D^{5} > 0, a_3 > 0 \) with Fokker-Planck equation (48)) and the (horizontal) Brownian motion for contour-enhancement in \( \mathbb{R}^3 \times S^2 \) (i.e. non-zero parameters in (58) are \( D^{33} > 0, D^{44} = D^{55} > 0 \) with Fokker-Planck equation (49)).

See Figure 10 for a visualization of typical Green’s functions of contour completion and contour enhancement in \( \mathbb{R}^d \times S^{d-1}, d = 2, 3 \).

### 8.2 Time Integrated Brownian Motions

In the previous subsection we have formulated the Brownian-motions (58) underlying all linear left-invariant convection-diffusion equations on HARDI data, with in particular the direction process for contour completion and (horizontal) Brownian motion for contour-enhancement. However, we only considered the time dependent stochastic processes and as mentioned before in Markov-processes traveling time is memoryless and thereby negatively exponentially
Figure 10: The Green’s function of Forward Kolmogorov equation of (the horizontal) direction process and the Green’s function of the Forward Kolmogorov equation of (horizontal) Brownian motion in $\mathbb{R}^d \times S^{d-1}$, for $d = 3$ as considered in this article and for $d = 2$ as considered in our previous work [32] (completion) and [29, 30] (enhancement).
distributed $T \sim NE(\lambda)$, i.e. $P(T = t) = \lambda e^{-\lambda t}$ with expectation $E(T) = \lambda^{-1}$, for some $\lambda > 0$. By means of Laplace-transform with respect to time we relate the time-dependent Fokker-Planck equations to their resolvent equations, as at least formally we have

$$W(y, n, t) = (e^{t(Q_{D,a}(\nabla))}U)(y, n)$$

and $P_\gamma(y, n, t) = \lambda \int_0^\infty e^{-t\lambda}(e^{t(Q_{D,a}(\nabla))}U)(y, n) = \lambda \lambda - Q^{D,a}(\nabla))^{-1}U(y, n)$, for $t, \lambda > 0$ and all $y \in \mathbb{R}^3$, $n \in S^2$, where the negative definite generator $Q^{D,a}$ is given by (43) and again with $\nabla U = (A_1 U, \ldots, A_6 U)^T$. The resolvent operator $\lambda (I - Q^{D,a}(\nabla))^{-1}$ occurs in a first order Tikhonov regularization as we show in the next theorem.

**Theorem 2** Let $U \in L_2(\mathbb{R}^3 \times S^2)$ and $\lambda, D^{33} > 0$, $D^{44} = D^{55} > 0$. Then the unique solution of the variational problem

$$\arg \min_{p \in \mathbb{R}^5(\mathbb{R}^3 \times S^2)} \int_{\mathbb{R}^3 \times S^2} \frac{\lambda}{2}(P(y, n) - U(y, n))^2 + \sum_{k=3}^5 D^{kk} | A_k P(y, n) |^2 dyd\sigma(n)$$

(59)

is given by $P_\lambda^U(y, n) = (R_D^\lambda \ast_{\mathbb{R}^3 \times S^2} U)(y, n)$, where the Green’s function $R_D^\lambda : \mathbb{R}^3 \times S^2 \to \mathbb{R}$ is the Laplace-transform of the heat-kernel with respect to time: $R_D^\lambda(y, n) = \lambda \int_0^\infty p_t^{D,a=0}(y, n)e^{-t\lambda} dt$ with $D = \text{diag} \{ D^{11}, \ldots, D^{55} \}$. $P_\lambda^U(y, n)$ equals the probability of finding a random walker in $\mathbb{R}^3 \times S^2$ regardless its traveling time at position $y \in \mathbb{R}^3$ with orientation $n \in S^2$ starting from initial distribution $U$ at time $t = 0$.

For a proof see [25]. Basically, $P_\lambda^U(y, n) = (R_D^\lambda \ast_{\mathbb{R}^3 \times S^2} U)(y, n)$ represents the probability density of finding a random walker at position $y$ with orientation $n$ given that it started from the initial distribution $U$ regardless its traveling time, under the assumption that traveling time is memoryless and thereby negatively exponentially distributed $T \sim NE(\lambda)$. There is however, a practical drawback due to the latter assumption: Both the time-integrated resolvent kernel of the direction process and the time-integrated resolvent kernel of the enhancement process suffer from a serious singularity at the unity element. In fact by some asymptotics one has

$$R_\lambda^{a=0, D=\text{diag}(0,0,D^{33},D^{44},D^{55})}(y, n) \sim \frac{1}{|y|^2} \text{ with } |g| = |(y,R_n)| \text{ for } |g|_{D^{33},D^{44},D^{55}} << 1,$n

and $R_\lambda^{a=(0,0,1), D=\text{diag}(0,0,0,D^{44},D^{55})}(0,0,z,n) \sim \frac{1}{z^2}$ for $0 < z << 1$,

where $|g|_{D^{33},D^{44},D^{55}}$ is the weighted modulus on $SE(3) = \mathbb{R}^3 \times SO(3)$. For details see Appendix D. These kernels can not be sampled using an ordinary mid-point rule. But even if the kernels are analytically integrated spatially and then numerically differentiated the kernels are too much concentrated around the singularity for visually appealing results.

### 8.2.1 A $k$-step Approach: Temporal Gamma Distributions and the Iteration of Resolvents

The sum $T$ of $k$ independent negatively exponentially distributed random variables $T_i \sim NE(\lambda)$ (all with expectation $E(T_i) = \lambda^{-1}$) is Gamma distributed:

$$T = \sum_{i=1}^k T_i \text{ with pdf } p(T = t) = p(T_1 = t) \cdot \ldots \cdot p(T_k = t) = \Gamma(t; k, \lambda) = \frac{\lambda^k t^{k-1}}{(k-1)!} e^{-\lambda t}, k \in \mathbb{N},$$

where we recall that temporal convolutions are given by $(f \ast_{\mathbb{R}^+} g)(t) = \int_0^t f(t-\tau)g(\tau) d\tau$ and note that application of the laplace transform $L$, given by $L(f)(\tau) = \int_0^\infty f(t)e^{-\lambda t} dt$ yields $L(f \ast_{\mathbb{R}^+} g) = L(f) \cdot L(g)$. Now for the sake of illustration we set $k = 2$ for the moment and we compute the probability density of finding a random walker with traveling time $T = T_1 + T_2$ at position $y$ with orientation $n$ given that it at $t = 0$ started at $(0)$ with orientation...
e_z. Basically this means that the path of the random walker has two stages, first one with time \( T_1 \sim NE(\lambda) \) and subsequently one with traveling time \( T_2 \sim NE(\lambda) \) and straightforward computations yield

\[
R^{D,a}_{\lambda,k=2}(y, n) = \int_0^\infty p(G_T = (y, n)|T = t \text{ and } G_0 = e) p(T = t) \, dt
\]

where we note that the Laplace transformation of a Gamma distribution equals

\[
\lambda^2 \mathcal{L} \left(t \mapsto \int_0^t (K_{t-s} * S^2) d\lambda e \right)(\lambda) = \lambda^2 \mathcal{L} \left(t \mapsto \int_0^t (K_{t-s} * S^2) d\lambda \right)(\lambda)
\]

By induction this can easily be generalized to the general case where we have

\[
R^{D,a}_{\lambda,k=2} = R^{D,a}_{\lambda} * R^{D,a}_{\lambda} \quad \text{with} \quad R^{D,a}_{\lambda} = R^{D,a}_{\lambda,k=1} \quad \text{and} \quad p(T = t) = (p(T_1 = \cdot) * p(T_2 = \cdot))(t).
\]

As an alternative to our probabilistic derivation one has the following derivation (which holds in distributional sense):

\[
R^{D,a}_{\lambda,k} = \int_0^\infty (e^{tQ^{D,a}(\nabla)}) \Gamma(t; k, \lambda) \, dt
\]

where we note that the Laplace transformation of a Gamma distribution equals

\[
\mathcal{L} \Gamma(\cdot; k, \lambda)(s) = (1 + \lambda^{-1} s)^{-k}.
\]

Figure 11: Glyph visualization, recall Def. 1, of the kernels \( R^{D,a}_{\lambda,k=2} : \mathbb{R}^3 \times S^2 \to \mathbb{R}^+ \), with diffusion matrix \( D = \text{diag}(0, 0, 0, D^{44}, D^{44}, 0) \) and convection vector \( a = (0, 0, 1, 0, 0, 0) \), for several parameter-settings \((\lambda, k)\) for \( D^{44} = 0.005 \). Kernels are sampled and computed on a spatial \( 8 \times 8 \times 8 \)-grid and on an a 162-point tessellation of the icosahedron using a left-invariant finite difference scheme, cf. [20]. For the sake of comparison we fixed the expected value of the Gamma-distribution to \( \frac{\lambda}{k} = 4 \). The glyph-visualization parameter \( \mu \) (which determines the global scaling of the glyphs) has been set manually in all cases.
Figure 12: Glyph visualization, recall Def. 1, of left-invariant finite difference scheme, on a $12 \times 12 \times 12$-grid and 162-point tessellation of the icosahedron, applied to the input data set, according to our time integrated contour-completion process, ref. Eq. (58), with diffusion matrix $D = \text{diag}\{0, 0, 0, D_{44}, D_{44}\}$, $D_{44} = 0.005$ and convection vector $\mathbf{a} = (0, 0, 1, 0, 0)$, iterated $k$-times with $E(T_i) = \lambda^{-1}, i = 1, \ldots, k$.

Figure 12 shows some experiments of contour completion on an artificial data set containing fibers with a gap we would like to complete, for various parameter settings of $(\lambda, k)$, where $T_i \sim \text{NE}(\lambda)$ and $k$ denotes the iteration index of the time integrated contour-completion process. In principle this scheme boils down to $\mathbb{R}^3 \rtimes \mathbb{S}^2$-convolution with the Green’s functions depicted in Fig. 13 (this is only approximately the case due to discretization). For a fair comparison we kept the expected value constant, that is $E(T) = E(T_1 + \ldots T_k) = \frac{k}{\lambda} = 4$ in Figure 11 and $E(T) = E(T_1 + \ldots T_k) = \frac{k}{\lambda} = 2$ in Figure 12, which roughly coincides with half the size of the gap. Note that the results hardly change after two iterations, as the graphs of the scaled Gamma distributions $\Gamma(\cdot; \frac{2}{2}, k)/\Gamma((2(k-1)/k); \frac{2}{2}, k)$ are similar for $k = 2, 3, 4, 5$.

8.3 Cost Processes on $SE(3)$

In this subsection we present a short overview of cost processes on $SE(3)$. The mapping $I \mapsto \lim_{\varepsilon \to 0} \log_\varepsilon I$ defines a morphism of the $(+, \cdot)$-algebra to the $(\min, +)$-algebra on $\mathbb{R}^+$ (the co-domain of our HARDI orientation scores, recall Def. 3) and it is indeed readily verified that $\lim_{\varepsilon \to 0} \log_\varepsilon e^a \cdot e^b = a + b$ and $\lim_{\varepsilon \to 0} \log_\varepsilon (e^a + e^b) = \min(a, b)$. Using this map, various notions of probability calculus can be mapped to their counterparts in optimization problems. Next we mention the following definitions as given by Akian, Quadrat and Viot in [2] adapted to our case.

**Definition 5** The decision space is the triplet $(SE(3), \mathcal{O}(SE(3)), C)$ with $\mathcal{O}(SE(3))$ denoting the set of all open subsets of the topological space $SE(3)$. The function $C : \mathcal{O}(SE(3)) \to \mathbb{R}^+ := \mathbb{R}^+ \cup \{\infty\}$ is such that
1. $C(SE(3)) = 0$
2. $C(\phi) = +\infty$
3. $C(\bigcup_n A_n) = \inf_n C(A_n)$ for any $A_n \in O(SE(3))$

$C$ is called a cost measure on $SE(3)$. The map $c : SE(3) \rightarrow \mathbb{R}^+$ given by $g \mapsto c(g)$ such that $C(A) = \inf_{g \in A} c(g)$ for all $A \subseteq SE(3)$, is called the cost density of the cost measure $C$.

**Definition 6** Analogous to the random variables of probability theory, a decision variable $G$ (on $(SE(3), O(SE(3)), C)$) is a mapping from $SE(3)$ to $\mathbb{R}$. It induces a cost measure $C_G$ on $\mathbb{R}$ given by $C_G(I) = C(G^{-1}(I))$ for all $I \in O(\mathbb{R})$. The associated cost density is denoted by $c_G$.

One can formulate related concepts such as independent decision variables, conditional cost, mean of a decision variable etc. in the same way as in probability theory keeping in mind the morphism of the $(+,\cdot)$-algebra to the $(\min, +)$-algebra. The Laplace or Fourier transform in $(+,\cdot)$-algebra corresponds to the Fenchel transform in the $(\min, +)$-algebra. Now we present the decision counterpart of the Markov processes, namely Bellman processes.

**Definition 7** A continuous time Bellman process $G_t$ on $(SE(3), O(SE(3)), C)$ is a function from $SE(3)$ to $C(\mathbb{R}^+)$ (set of continuous functions on non negative reals) with cost density

$$c_G(\tilde{\gamma}(\cdot)) = c_0(\tilde{\gamma}(0)) + \int_0^\infty c(t, \tilde{\gamma}(t), \tilde{\gamma}'(t)) \, dt$$

(61)

where $c$ is called the transition cost which is a map from $\mathbb{R} \times SE(3) \times T(SE(3))$ to $\mathbb{R}^+$ such that

$$\inf_{\mathcal{A} \in L(SE(3))} c(t, g, \mathcal{A}|_g) = 0 \text{ for all } (t, g) \in \mathbb{R}^+ \times SE(3),$$

and where $c_0$ is some cost density on $SE(3)$.

We set

$$c(t, \tilde{\gamma}(t), \tilde{\gamma}'(t)) = \sum_{i \in \{1,2,4,5\}} |\langle d_i \mathcal{A} |_{\tilde{\gamma}(t)} \rangle, \tilde{\gamma}'(t) |^2.$$

Then the marginal cost for a Bellman process $G_t$ on $(SE(3), O(SE(3)), C)$ to be in a state $g$ at time $t$ given an initial cost $c_0$, $\tilde{m}(g, t) := C(G_t = g)$ satisfies the following relation known as the Bellman equation

$$\partial_t \tilde{m} + (F_{L(SE(3))}(L))(d\tilde{m}) = 0,$$

$$\tilde{m}(g, 0) = c_0(g)$$

(62)

where $F_{L(SE(3))}$ denotes the Fenchel transform, see Appendix B, Definition 9, on the Lie-Algebra $L(SE(3))$ of left-invariant vector fields and where

$$L(A) = \sum_{i \in \{1,2,4,5\}} \frac{1}{2} |\langle d_i \mathcal{A} | \rangle|^2,$$

$$d\tilde{m} = \sum_{i \in \{1,2,4,5\}} A_i \tilde{m} \, dA^i$$

for all $A$ left-invariant vector fields within contact-manifold $(SE(3), d\mathcal{A}^3, d\mathcal{A}^6)$ and with left-invariant gradient of $\tilde{m}$ within $(SE(3), d\mathcal{A}^3, d\mathcal{A}^6)$. This Bellman equation for the cost process coincides with the Hamilton-Jacobi equation on $SE(3)$ (135) whose viscosity solution is given by morphological convolution with the corresponding morphological Green’s function as proven in Appendix B.
9 Differential Geometry: The underlying Cartan-Connection on $SE(3)$ and the Auto-Parallels in $SE(3)$

Now that we have constructed all left-invariant scale space representations on HARDI images, generated by means of a quadratic form $Q$ on the left-invariant vector fields on $SE(3)$. The question rises what is the underlying differential geometry for these evolutions?

For example, as the left-invariant vector fields clearly vary per position in the group yielding a moving frame of reference attached to luminosity particles (random walkers in $\mathbb{R}^3 \times S^2$ embedded in $SE(3)$) with both a position and an orientation, the question rises along which trajectories in $\mathbb{R}^3 \times S^2$ do these particles move? Furthermore, as the left-invariant vector fields are obtained by the push-forward of the left-multiplication on the group,

$$A_g = (L_g)_* A_c, \text{ i.e. } A_g \hat{\phi} = A_c (\hat{\phi} \circ L_g), \text{ where } L_g h = gh, \ g, h \in SE(3), \hat{\phi} : SE(3) \to \mathbb{R} \text{ smooth},$$

the question rises whether this defines a connection between all tangent spaces, such that these trajectories are auto-parallel with respect to this connection? Finally, we need a connection to rigid body mechanics described in a moving frame of reference, to get some physical intuition in the choice of the fundamental constants $\{a_i\}_{i=1}^6$ and $\{D^{ij}\}_{i,j=1}$ within our generators $Q$.

In order to get some first physical intuition on analysis and differential geometry along the moving frame of reference, we make some preliminary remarks on the well-known theory of rigid body movements described in moving coordinate systems. Imagine a curve in $\mathbb{R}^3$ described in the moving frame of reference (embedded in the spatial part of the group $SE(3)$), describing a rigid body movement with constant spatial velocity $\dot{c}^{(1)}$ and constant angular velocity $\dot{c}^{(2)}$ and parameterized by arc-length $s > 0$. Suppose the curve is given by

$$y(s) = \sum_{i=1}^{3} \alpha_i(s) A_i|_{y(s)} \text{ where } \alpha_i \in C^2([0, L], \mathbb{R}),$$

such that $\dot{c}^{(1)} = \sum_{i=1}^{3} \alpha_i(s) A_i|_{y(s)}$ for all $s > 0$. Now if we differentiate twice with respect to the arc-length parameter and keep in mind that $\frac{d}{ds} A_i|_{y(s)} = \ddot{c}^{(2)} \times A_i|_{y(s)}$, we get

$$\ddot{y}(s) = 0 + 2\ddot{c}^{(2)} \times \dot{c}^{(1)} + \dddot{c}^{(2)} \times (\dddot{c}^{(2)} \times y(s)).$$

In words: The absolute acceleration equals the relative acceleration (which is zero, since $\dot{c}^{(1)}$ is constant) plus the Coriolis acceleration $2\dddot{c}^{(2)} \times \dot{c}^{(1)}$ and the centrifugal acceleration $\dddot{c}^{(2)} \times (\dddot{c}^{(2)} \times y(s))$. When in uniform circular motion the speed is constant but the velocity is always tangent to the orbit of acceleration and the acceleration has constant magnitude and always points to the center of rotation. In this case, the total sum of Coriolis acceleration and centrifugal acceleration add up to the well-known centripetal acceleration,

$$\ddot{y}(s) = 2\dddot{c}^{(2)} \times (\dddot{c}^{(2)} \times \dot{Rr}(s)) + \dddot{c}^{(2)} \times (\dddot{c}^{(2)} \times \dot{Rr}(s)) = -\|\dddot{c}^{(2)}\|^2 \dot{Rr}(s) = -\frac{\|\dddot{c}^{(2)}\|^2}{R} \dot{r}(s),$$

where $R$ is the radius of the circular orbit $y(s) = m + R \dot{r}(s), \ | \dot{r}(s) \| = 1).$ The centripetal acceleration equals half the Coriolis acceleration, i.e. $\ddot{y}(s) = \dddot{c}^{(2)} \times \dot{c}^{(1)}$.

In our previous work [29, part II] on contour-enhancement and completion via left-invariant diffusions on invertible orientation scores (complex-valued functions on $SE(2)$) we put a lot of emphasis on the underlying differential geometry in $SE(2)$. All results straightforwardly generalize to the case of HARDI images, which can be considered as functions on $\mathbb{R}^3 \times S^2$ embedded in $SE(3)$. These rather technical results are summarized in Theorem 3, which answers all questions raised in the beginning of this section. Unfortunately, this theorem requires general differential
The Maurer-Cartan form \( \omega \) is given by

\[
\omega_g(X_g) = \sum_{i=1}^{6} (dA^i)_{ij} \otimes X_j, \quad X_g \in T_g(SE(3)),
\]

where the dual vectors \( \{dA^i\}_{i=1}^{6} \) are given by (7) and \( A_i = A_i^\gamma \). It is a Cartan Ehresmann connection form on the principal fiber bundle \( P = (SE(3), \pi : SE(3) \to e \equiv SE(3)/SE(3), SE(3)) \), where \( \pi(g) = e, R_{g} u = u, u, g \in SE(3) \). Let \( Ad \) denote the adjoint action of \( SE(3) \) on its own Lie-algebra \( \mathfrak{se}(SE(3)) \), i.e. \( Ad(g) = (R_{g} - 1) L_{g} \), i.e. the push-forward of conjugation. Then the adjoint representation of \( SE(3) \) on the vector space \( \mathcal{L}(SE(3)) \) of left-invariant vector fields is given by

\[
\tilde{Ad}(g) = dR \circ Ad(g) \circ \omega.
\]

This adjoint representation gives rise to the associated vector bundle \( SE(3) \times_{Ad} \mathcal{L}(SE(3)) \). The corresponding connection form on this vector bundle is given by

\[
\tilde{\omega} = \sum_{j=1}^{6} \tilde{ad}(A_j) \otimes dA^j = \sum_{i,j,k=1}^{6} c^k_{ij} A_k \otimes dA^i \otimes dA^j,
\]

with \( \tilde{ad} = (\tilde{Ad})^* \), i.e. \( \tilde{ad}(A_j) = \sum_{i=1}^{6} [A_i, A_j] \otimes dA^i \). Then \( \tilde{\omega} \) yields the following 6×6-matrix valued 1-form

\[
\tilde{\omega}^k_{ij}(\cdot) := -\tilde{\omega}(dA^k, \cdot, A_j) \quad k, j = 1, 2, \ldots, 6.
\]

The adjoint representation is given by (66) and the Cartan connection given by the covariant derivatives

\[
D_X|_{\gamma(t)}(\mu(\gamma(t))) := D\mu(\gamma(t))(X|_{\gamma(t)}) = \sum_{k=1}^{6} a^k(t) \mu_k(\gamma(t)) + \sum_{k=1}^{6} a^k(\gamma(t)) \sum_{j=1}^{6} \tilde{\omega}^j_{ik}(X|_{\gamma(t)}) \mu_j(\gamma(t)) = \sum_{k=1}^{6} a^k(t) \mu_k(\gamma(t)) + \sum_{k=1}^{6} \tilde{\omega}^j_{ik}(A_k) \mu_j(\gamma(t))
\]

\( \text{3} \)The torsion tensor \( T^\nabla \) of a connection \( \nabla \) is given by \( T^\nabla[X, Y] = \nabla_X Y - \nabla_Y X - [X, Y] \). The torsion-tensor of \( T^\nabla \) of a Levi-Civita connection vanishes, whereas the torsion-tensor of our Cartan connection \( \nabla \) on \( SE(3) \) is given by \( T^\nabla = \sum_{i,j,k=1}^{6} c^k_{ij} dA^i \otimes dA^j \).\( \text{4} \)In a Levi-Civita connection one has \( \Gamma^k_{ij} = \Gamma^k_{ji} = \frac{1}{2} \sum_{m=1}^{6} g^{mn}(g_{mk,t} + g_{ml,k} - g_{kl,m}) \) with respect to a holonomic basis.
with \( \dot{a}^k(t) = \sum_{i=1}^6 \dot{\gamma}^i(t) (A_i|_{\gamma(t)}) a^k \), for all tangent vectors \( X|_{\gamma(t)} = \sum_{i=1}^6 \dot{\gamma}^i(t) A_i|_{\gamma(t)} \) along a curve \( t \mapsto \gamma(t) \in SE(2) \) and all sections \( \mu(\gamma(t)) = \sum_{k=1}^6 a^k(\gamma(t)) \phi_k(\gamma(t)) \). The Christoffel symbols in (67) are constant \( \Gamma_{ik}^j = -c_{ik}^j \), with \( c_{ik}^j \) the structure constants of Lie-algebra \( T\gamma(SE(3)) \). Consequently, the connection \( D \) has constant curvature and constant torsion and the left-invariant evolution equations given in Eq. (42) can be rewritten in covariant derivatives (using short notation \( \nabla_j := D_{A_j} \)):

\[
\begin{aligned}
\partial_t W(g, t) &= \sum_{i=1}^6 -a^i(W)A_iW(g, t) + \sum_{i,j=1}^6 A_i ((D^{(j)}(W))(g, t)A_j W)(g, t) \\
&= \sum_{i=1}^6 -a^i(W)\nabla_i W(g, t) + \sum_{i,j=1}^6 \nabla_i ((D^{(j)}(W))(g, t)\nabla_j W)(g, t) \\
W(g, 0) &= \tilde{U}(g) , \quad \text{for all } g \in SE(3), t > 0.
\end{aligned}
\] (68)

Both convection and diffusion in the left-invariant evolution equations (42) take place along the exponential curves \( \gamma_{c,g}(t) = g \cdot e^{-t \sum_{i=1}^6 c_i A_i} \) in \( SE(3) \) which are the covariantly constant curves (i.e. auto-parallel) with respect to the Cartan connection. In particular, if \( a^i(W) = c^i \) constant and if \( D^{(j)}(W) = 0 \) (convection case) then the solutions are

\[
W(g, t) = \tilde{U}(g \cdot e^{-t \sum_{i=1}^6 c_i A_i}).
\] (69)

The spatial projections \( P_{\mathbb{R}^3}\gamma \) of these of the auto-parallel/exponential curves \( \gamma \) are circular spirals with constant curvature and constant torsion. The curvature magnitude equals \( \|c^{(1)}\|^{-1} \|\hat{c}^{(2)} \times c^{(1)}\| \) and the curvature vector equals

\[
\kappa(t) = \frac{1}{\|c^{(1)}\|} \left( \cos(t \|\hat{c}^{(2)}\|) \hat{c}^{(2)} \times \hat{c}^{(1)} + \frac{\sin(t \|\hat{c}^{(2)}\|)}{\|\hat{c}^{(2)}\|} \hat{c}^{(2)} \times \hat{c}^{(2)} \times \hat{c}^{(1)} \right),
\] (70)

where \( c = (c^1, c^2, c^3; c^4, c^5, c^6) = (\hat{c}^{(1)}; \hat{c}^{(2)}) \). The torsion vector equals \( \tau(t) = |\hat{c}_1 \cdot \hat{c}_2| \kappa(t) \).

**Proof** The proof is a straightforward generalization from our previous results [29, Part II, Thm 3.8 and Thm 3.9] on the \( SE(2) \)-case to the case \( SE(3) \). The formulas of the constant torsion and curvature of the spatial part of the auto-parallel curves (which are the exponential curves) follow by the formula (71) for (the spatial part \( x(s) \) of) the exponential curves, which we will derive in Section 9.1. Here we stress that \( s(t) = t \sqrt{(c^1)^2 + (c^2)^2 + (c^3)^2} \) is the arc-length of the spatial part of the exponential curve and where we recall that \( \kappa(s) = \dot{x}(s) \) and \( \tau(s) = \frac{\dot{x}}{||\dot{x}||} (x(s) \times \dot{x}(s)) \). Note that both the formula (71) for the exponential curves in the next section and the formulas for torsion and curvature are simplifications of our earlier formulas [38, p.175-177]. In the special case of only convection the solution (69) follows by \( e^{i\Omega(t)} \tilde{U}(g) = R_{e^{\Omega(t)}} \tilde{U}(g) \), with \( A = -\sum_{i=1}^6 c^i A_i \) and \( dR(A) = -\sum_{i=1}^6 c^i A_i \) with \( A_i = dR(A_i) \).

### 9.1 The Exponential Curves and the Logarithmic Map explicitly in Euler Angles

The surjective exponent mapping is given by

\[
\gamma_{c}(t) = e^{\sum_{i=1}^6 c_i A_i} = \left\{ \begin{array}{c}
(c_1 t, c_2 t, c_3 t, t) \text{ if } \hat{c}^{(2)} = 0 , \\
(t\hat{c}^{(1)} + \frac{1 - \cos(qt)}{q^2} \Omega \hat{c}^{(1)}) + (tq - \frac{\sin(qt)}{q}) \Omega^2 \hat{c}^{(1)} , I + \frac{\sin(qt)}{q} \Omega + \frac{(1 - \cos(qt))}{q^2} \Omega^2 \text{ else}.
\end{array} \right.
\] (71)

where \( \tilde{q} = \|\hat{c}^{(2)}\| = \sqrt{(c^1)^2 + (c^5)^2 + (c^6)^2} \) and \( \Omega x = \hat{c}^{(2)} \times x \) for all \( x \in \mathbb{R}^3 \).
The logarithmic mapping on $SE(3)$ is given by:

$$
\log_{SE(3)}(x, R_{\gamma,\beta,\alpha}) = \sum_{i=1}^{3} c^{i}_{x,\gamma,\beta,\alpha} A_i + \sum_{i=4}^{6} c^{i}_{\gamma,\beta,\alpha} A_i
$$

(72)

Expressed in the first chart (using short notation $\tilde{c}^i := c^{i}_{x,\gamma,\beta,\alpha}$) we have

$$
\tilde{q} = \arcsin \sqrt{\cos^2 \left( \frac{\alpha + \gamma}{2} \right) \sin^2 \beta + \cos^4 \left( \frac{\beta}{2} \right) \sin^2 (\alpha + \gamma)}
$$

$$
\tilde{c}^{(2)} := (c^4, c^5, c^6)^T = \frac{\tilde{q}}{2 \sin \tilde{q}} \left( \sin \beta (\sin \alpha - \sin \gamma), \sin \beta (\cos \alpha + \cos \gamma), 2 \cos^2 \left( \frac{\tilde{q}}{2} \right) \sin (\alpha + \gamma) \right)
$$

(73)

and

$$
\tilde{c}^{(1)} = (c^1, c^2, c^3)^T = x - \frac{1}{2} \tilde{c}^{(2)} \times x + \tilde{q}^{-2} (1 - (\frac{\tilde{q}}{2}) \cot(\frac{\tilde{q}}{2})) \tilde{c}^{(2)} \times (\tilde{c}^{(2)} \times x).
$$

(74)

with $\tilde{c}^{(1)} = (c^1, c^2, c^3)$, $\tilde{c}^{(2)} = (c^4, c^5, c^6)$.

Throughout this article we will take the section $\alpha = 0$ (this is just a choice, we could have taken another section) in the partition $\mathbb{R}^3 \times S^2 / (\{0\} \times SO(2))$, which means that we will only consider the case

$$
(\tilde{c}^{(1)} ; \tilde{c}^{(2)}) \big|_{\alpha=0} = (c^{1}_{x,\gamma,\beta,\alpha=0}, c^{2}_{x,\gamma,\beta,\alpha=0}, c^{3}_{x,\gamma,\beta,\alpha=0}, c^{4}_{x,\gamma,\beta,\alpha=0}, c^{5}_{x,\gamma,\beta,\alpha=0}, c^{6}_{x,\gamma,\beta,\alpha=0}).
$$

Expressed in the second chart the section $\tilde{\alpha} = 0$ coincides with the section $\alpha = 0$ and along this section we again have (74) but now with

$$
\tilde{q} = \arcsin \sqrt{\cos^4(\tilde{\gamma}/2) \sin^2(\tilde{\beta}) + \cos^2(\tilde{\beta}/2) \sin^2(\tilde{\gamma})},
$$

$$
\tilde{c}^{(2)} = (c^4, c^5, c^6)^T = \frac{\tilde{q}}{2 \sin(\tilde{q})} \left( \sin \tilde{\gamma} \cos^2 \left( \frac{\tilde{\beta}}{2} \right), \sin \tilde{\beta} \cos^2 \left( \frac{\tilde{\gamma}}{2} \right), \frac{1}{2} \sin \tilde{\gamma} \sin \tilde{\beta} \right)^T,
$$

(75)

where we again used short notation $\tilde{c}^i := \tilde{c}^i_{x,\gamma,\beta,\alpha=0}$. Roughly speaking, $\tilde{c}^{(1)}$ is the spatial velocity of the exponential curve (fiber) and $\tilde{c}^{(2)}$ is the angular velocity of the exponential curve (fiber).

10 Analysis of the Convolution Kernels of Scale Spaces on HARDI images

It is notorious problem to find explicit formulas for the exact Green’s functions $p_{t}^{D,a} : \mathbb{R}^3 \times S^2$ of the left-invariant diffusions (44) on $\mathbb{R}^3 \times S^2$. Explicit, tangible and exact formulas for heat-kernels on $SE(3)$ do not seem to exist in literature. Nevertheless, there does exist a nice general theory overlapping the fields of functional analysis and group theory, see for example [67, 54], which at least provides Gaussian estimates for Green’s functions of left-invariant diffusions on Lie groups, generated by subcoercive operators. In the remainder of this section we will employ this general theory to our special case where $\mathbb{R}^3 \times S^2$ is embedded into $SE(3)$ and we will derive new explicit and useful approximation formulas for these Green’s functions. Within this section we use the second coordinate chart (15), as it is highly preferable over the more common Euler angle parametrization (12) because of the much more suitable singularity locations on the sphere.

We shall first carry out the method of contraction. This method typically relates the group positions and rotations to a (nilpotent) group positions and velocities and serves as an essential pre-requisite for our Gaussian estimates and approximation kernels later on. The reader who is not so much interested in the detailed analysis can skip this section and continue with the numerics explained in Chapter 12.
10.1 Local Approximation of $SE(3)$ by a Nilpotent Group via Contraction

The group $SE(3)$ is not nilpotent. This makes it hard to get tangible explicit formulae for the heat-kernels. Therefore we shall generalize our Heisenberg approximations of the Green’s functions on $SE(2)$, [32], [64],[4], to the case $SE(3)$. Again we will follow the general work by ter Elst and Robinson [67] on semigroups on Lie groups generated by weighted subcoercive operators. In their general work we consider a particular case by setting the Hilbert space $L^2(SE(3))$, the group $SE(3)$ and the right-regular representation $R$. Furthermore we consider the algebraic basis \( \{ A_3, A_4, A_5 \} \) leading to the following filtration of the Lie algebra

\[
g_1 = \text{span}\{ A_3, A_4, A_5 \} \subset g_2 = \text{span}\{ A_1, A_2, A_3, A_4, A_5, A_6 \} = \mathcal{L}(SE(3)).
\]

Now that we have this filtration we have to assign weights to the generators

\[
w_3 = w_4 = w_5 = 1 \quad \text{and} \quad w_1 = w_2 = w_6 = 2.
\]

For example $w_3 = 1$ since $A_3$ already occurs in $g_1$, $w_6 = 2$ since $A_6$ is within in $g_2$ and not in $g_1$.

Now that we have these weights we define the following dilations on the Lie-algebra $T_e(SE(3))$ (recall $A_i = A_i|_{g_0}$):

\[
\gamma_q^{\alpha} \left( \sum_{i=1}^{6} c_i A_i \right) = \sum_{i=1}^{6} q^{w_i} c_i A_i, \quad \text{for all} \quad c_i \in \mathbb{R},
\]

\[
\tilde{\gamma}_q(x, y, z, R_{\tilde{\gamma}, \tilde{\alpha}, \tilde{\beta}}) = \left( \frac{x}{\tilde{\gamma}^3}, \frac{y}{\tilde{\gamma}^3}, \frac{z}{\tilde{\gamma}^3}, R_{\tilde{\gamma}, \tilde{\alpha}, \tilde{\beta}} \cdot \frac{x}{\tilde{\gamma}^3}, \frac{y}{\tilde{\gamma}^3}, \frac{z}{\tilde{\gamma}^3} \right), \quad q > 0,
\]

and for $0 < q \leq 1$ we define the Lie product $[A, B]_q = \gamma_q^{-1}[\gamma_q(A), \gamma_q(B)]$. Now let $(SE(3))_q$ be the simply connected Lie group generated by the Lie algebra $(T_e(SE(3)), [\cdot, \cdot]_q)$. This Lie group is isomorphic to the matrix group with group product:

\[
(x, R_{\tilde{\gamma}, \tilde{\beta}, \tilde{\alpha}})_q (x', R_{\tilde{\gamma}', \tilde{\beta}', \tilde{\alpha}}) = (x + S_q \cdot R_{\tilde{\gamma}, \tilde{\beta}, \tilde{\alpha}} \cdot S_q^{-1} \cdot x', \tilde{R}_{\tilde{\gamma}, \tilde{\beta}, \tilde{\alpha}} \cdot R_{\tilde{\gamma}', \tilde{\beta}', \tilde{\alpha}})
\]

(78)

where the diagonal $3 \times 3$-matrix is defined by $S_q := \text{diag}(1, 1, q)$ and we used short notation $R_{\tilde{\gamma}, \tilde{\beta}, \tilde{\alpha}} = R_{e, \tilde{\gamma}, \tilde{e}} R_{e, \tilde{\beta}, \tilde{e}} R_{e, \tilde{\alpha}, \tilde{e}}$, i.e. our elements of $SO(3)$ are expressed in the second coordinate chart (15). Now the left-invariant vector fields on the group $(SE(3))_q$ are given by

\[
A_i^q|_g = (\tilde{\gamma}_q^{-1} \circ L_g \circ \tilde{\gamma}_q)_* A_i, \quad i = 1, \ldots, 6.
\]

Straightforward (but intense) calculations yield (for each $g = (x, R_{\tilde{\gamma}, \tilde{\beta}, \tilde{\alpha}}) \in (SE(3))_q$):

\[
A_1^q|_g = \cos(q^2 \tilde{\alpha}) \cos(q \tilde{\beta}) \partial_x + (\cos(q \tilde{\gamma}) \sin(q^2 \tilde{\alpha}) + \cos(q^2 \tilde{\alpha}) \sin(q \tilde{\beta}) \sin(q \tilde{\gamma})) \partial_y + q \sin(q \tilde{\alpha}) \sin(q \tilde{\gamma}) \partial_z
\]

\[
A_2^q|_g = -
\]

\[
A_3^q|_g = q^{-1} \sin(q \tilde{\alpha}) \partial_x - q^{-1} \cos(q \tilde{\alpha}) \sin(q \tilde{\gamma}) \partial_y + \cos(q \tilde{\alpha}) \cos(q \tilde{\beta}) \partial_z
\]

\[
A_4^q|_g = q^{-1} \cos(q \tilde{\alpha}) \tan(q \tilde{\beta}) \partial_x + \sin(q \tilde{\alpha}) \partial_y + \frac{\cos(q \tilde{\alpha}) \cos(q \tilde{\beta}) \partial_z}{\cos(q \tilde{\beta})}
\]

\[
A_5^q|_g = q^{-1} \sin(q \tilde{\alpha}) \tan(q \tilde{\beta}) \partial_x + \cos(q \tilde{\alpha}) \partial_y - \frac{\sin(q \tilde{\alpha}) \partial_z}{\cos(q \tilde{\beta})}
\]

\[
A_6^q|_g = \partial_z.
\]

Now note that $[A_1, A_2]_q = \gamma_q^{-1}[\gamma_q(A_1), \gamma_q(A_2)] = \gamma_q^{-1}q^{w_1+w_2} [A_1, A_2] = \sum_{k=1}^{6} q^{w_1+w_2-w_k} c_{ij} k A_k$ and thereby we have

\[
\begin{array}{l}
[A_4, A_2]_q = A_6, \\
[A_4, A_4]_q = q^3 A_3, \\
[A_5, A_6]_q = q^3 A_4, \\
[A_4, A_3]_q = -A_2, \\
[A_4, A_2]_q = q^3 A_3, \\
[A_5, A_1]_q = -q^3 A_3, \\
[A_4, A_3]_q = A_1, \\
[A_6, A_1]_q = q^3 A_2 \\
[A_5, A_2]_q = -q^3 A_1.
\end{array}
\]

(79)

Similarly for $q = 1$, $(SE(3))_{q=1} = SE(3)$ we have an isomorphism of the common Lie-algebra at the unity element $T_e(SE(3)) = T_e((SE(3))_q)$ and left-invariant vector fields on the group $(SE(3))_q$:

\[
(A_i \leftrightarrow A_i^q \text{ and } A_j \leftrightarrow A_j^q) \Rightarrow [A_i, A_j]_q \leftrightarrow [A_i^q, A_j^q].
\]

34
It can be verified that the left-invariant vector fields $A_i^q$ satisfy the same commutation relations (79).

Now let us consider the case $q \downarrow 0$, then we get a nilpotent-group $(SE(3))_0$ with left-invariant vector fields

$$A_1^q = \partial_x, \quad A_2^q = \partial_y, \quad A_3^q = \beta \partial_x - \gamma \partial_y + \partial_z, \quad A_4^q = -\beta \partial_\alpha + \partial_\gamma, \quad A_5^q = \partial_\beta, \quad A_6^q = \partial_\alpha. \quad (80)$$

### 10.1.1 The Heisenberg-approximation of the Time-integrated $k$-step Contour Completion Kernel

Recall that the generator of contour completion diffusion equals $A_3 + D^{44}((A_4)^2 + (A_5)^2)$. So let us replace the true left-invariant vector fields $\{A_i\}_{i=3}^5$ on $SE(3) = (SE(3))_{g=1}$ by their Heisenberg-approximations $\{A_i^q\}_{i=3}^5$ that are given by (80) and compute the Green’s function $p_{t_3}^{A_3 = 1, D^{44} = D^{35}}$ on $(SE(3))_0$ (i.e. the convolution kernel which yields the solutions of contour completion on $(SE(3))_0$ by group convolution on $(SE(3))_0$). For $0 < D^{44} << 1$ this kernel is a local approximation of the true contour completion kernel and means that we now have the same direct-product approximation for the exact contour-enhancement kernels on $SE(3)$.

Now since the Heisenberg-approximation kernel $p_{t}^{A_3 = 1, D^{44} = D^{35}}$ is for reasonable parameter settings (that is $0 < \frac{D^{44}}{D^{35}} << 1$) close to the exact kernel $p_{t}^{D^{33}, D^{44} : (SE(2))_0}$ we heuristically propose for these reasonable parameter settings the same direct-product approximation for the exact contour-enhancement kernels on $\mathbb{R}^3 \times S^2$:

$$p_{t}^{D^{33}, D^{44} : (SE(2))_0} \approx N(D^{33}, D^{44}, t) \cdot p_{t}^{D^{33}, D^{44} : (SE(2))_{(z/2, x, \tilde{\beta}, \tilde{\gamma})} \cdot p_{t}^{D^{33}, D^{44} : (SE(2))_{(z/2, -y, \tilde{\gamma})}}, \quad (83)$$

where

$$N(D^{33}, D^{44}, t) \approx \frac{1}{8\sqrt{2}} \sqrt{\pi t} \sqrt{D^{33}} \sqrt{D^{44}} \quad (84)$$

The superscript for the kernel is actually $p_{t}^{D^{33}, D^{44}}$ so in the superscript-labels, for the sake of simplicity, we only mention the non-zero coefficients $D^{(3), \alpha}$ of (44).

Note that the delta distribution $\delta(z - s)$ allowed us to replace all $s$ by $z$ in the remaining factor in (81) which makes it easy to apply the integration $\int_{\mathbb{T}^1}^{t_{35}^{D^{33}, D^{44}}(t; k, \lambda)} \Gamma(t; k, \lambda) dt$.  

---

35
that these constants are computed by the logarithm on SE(3). In [25, ch:6.2] it is shown that the constants are very close and that a reasonably sharp approximation and upper bound of the horizontal diffusion kernel on \( \mathbb{R}^3 \times S^2 \) is given by

\[
p_t^{D_{33}, D_{44}}(x, y, \theta) \approx e^{-\frac{1}{4\pi^2 t} \left( \frac{|x|^2}{D_{33}} + \frac{|y|^2}{D_{44}} \right)} \frac{|(x, R\tilde{\eta})|^2_{D_{33}, D_{44}}}{4 \pi^2 t^{D_{33} D_{44}}},
\]

where one can use the estimate \( \frac{\theta/2}{\tan(\theta/2)} \approx \frac{\cos(\theta/2)}{1-\theta^2/24} \) for \( |\theta| < \frac{\pi}{10} \) to avoid numerical errors.

### 10.2 Gaussian Estimates for the Heat-kernels on SE(3)

In [25, ch:6.2] it is shown that the constants \( \tilde{C}_3, \tilde{C}_4 \) are very close and that a reasonably sharp approximation and upper bound of the horizontal diffusion kernel on \( \mathbb{R}^3 \times S^2 \) is given by

\[
p_t^{D=\text{diag}(0,0,D_{33},D_{44}), D_{55},0}(y, \tilde{n}(\tilde{\beta}, \tilde{\gamma})) \approx e^{-\frac{|(x, R\tilde{\eta})|^2_{D_{33}, D_{44}}}{4 \pi^2 t^{D_{33} D_{44}}}},
\]

with weighted modulus

\[
|\langle y, Rn \rangle|^2_{D_{33}, D_{44}} := \frac{|c|^2 + |d|^2}{D_{33} D_{44}} + \frac{|e|^2 |(c^3)\bar{D}_{33} + |e|^2 |(c^4)\bar{D}_{44}}{D_{33} D_{44}} + \frac{|c|^2}{D_{44}} + \frac{|c|^2}{D_{44}}
\]

where \( n = \tilde{n}(\tilde{\beta}, \tilde{\gamma}) \in S^2 \) and where we again use short notation \( c^k := c^k_{q=1}(x, R\tilde{\eta}, \beta, 0), k = 1, \ldots, 6. \) Recall from Section 9.1 that these constants are computed by the logarithm (72) on SE(3) or more explicitly by (75).

### 10.3 Analytic estimates for the Green’s functions of the Cost Processes on \( \mathbb{R}^3 \times S^2 \)

In Appendix B we have derived the following analytic approximation for the Green’s function \( k_t^{D_{11}, D_{44}, \eta, \pm}(y, \tilde{n}(\tilde{\beta}, \tilde{\gamma})) \) of the Hamilton-Jacobi equation (135) and corresponding cost-process explained in Section 8.3, Eq. (62) on \( \mathbb{R}^3 \times S^2 \):

\[
k_t^{D_{11}, D_{44}, \eta, \pm}(y, \tilde{n}(\tilde{\beta}, \tilde{\gamma})) \equiv \pm \frac{2\eta - 1}{2\eta} C^{2\eta} t^{-\frac{1}{2\eta - 1}} \left( \sum_{i=1}^{6} \frac{|c|^2 |(c^\tilde{n}(\tilde{\beta}, \tilde{\gamma}))|^2}{D_{ii}} \right)^{\frac{1}{2\eta}}
\]

for sufficiently small time \( t > 0 \), with weights \( w_1 = w_2 = w_4 = w_5 = 1, w_3 = w_6 = 2 \) and \( 2 > C > 0 \) and where the \( (c^1, \ldots, c^6) \) are given by (75) and where we have set \( n = \tilde{n}(\tilde{\beta}, \tilde{\gamma}) \) and \( c^k := c^k_{q=1}(y, R\tilde{\eta}, \beta, 0). \) Here we recall that \( D_{33} \) tunes the spatial erosion orthogonal to fibers, \( D_{44} \) tunes angular erosion and \( \eta \in \left( \frac{1}{2}, 1 \right) \) relates homogeneous erosion \( \eta = \frac{1}{2} \) to standard quadratic erosion \( \eta = 1 \).

Now analogously to our approach on SE(2) in [29, Ch:5.4] we use the estimate

\[
|a| + |b| \geq \sqrt{|a|^2 + |b|^2} \geq \frac{1}{\sqrt{2}} (|a| + |b|)
\]
two types of left-invariant evolutions are supposed to be alternated, So far we have considered anisotropic diffusions aligned with fibers and erosions orthogonal to the fibers. As these

\[ R_{11} \] \text{Pseudo Linear Scale Spaces on } \mathbb{R}^3 \text{, ideally}

\[ m \]

where we used the following identities

\[ D_{11} \text{, } D_{44} = 1 \]

and for \( \eta = \frac{1}{2} \) we obtain the flat analytic local approximation (that arises by taking the limit \( \eta \downarrow \frac{1}{2} \)):

\[ k_t^{D_{11}, D_{44}, \eta,+}(y, n) \approx \begin{cases} \infty & \text{if } \left( \frac{|c_1|^2 + |c_2|^2}{D_{11}^2} + \frac{|c_3|^2 + |c_4|^2}{D_{44}^2} \right) \geq t^2 \\
0 & \text{else} \end{cases} \]

See Figure 13 for glyph visualizations (recall Definition 1) of the erosion and corresponding diffusion kernel

\[ p_t^{D = \text{diag}(D_{11}, D_{11}, D_{44}, D_{44}, 0)} = e^{c(D_{11}((\Delta_{e^3} - (A_3)^2)) + D_{44} \Delta_{e^3} \delta_0)} \delta_0 \otimes \delta_{\kappa_z} \]

on the contact manifold \((\mathbb{R}^3 \times S^2, dA_3)\). In order to study the accuracy of this approximation formula for the case of angular erosion only (i.e. \( D_{11} = 0 \)) we have analytically computed

\[ m(\bar{\beta}, \bar{\gamma}) = \frac{1}{4} \frac{\partial_{\kappa_z} k_{t}^{D_{11} = 0, D_{44} = 1}}{\partial_{\kappa_z} k_{t}^{D_{11} = 0, D_{44} = 1}} \]

where we used the following identities

\[ |A_3 U|^2 + |A_3 U|^2 = |\partial_\beta U|^2 + (\cos \bar{\beta})^{-2} |\partial_\beta U|^2 \]

\[ |A_1 U|^2 + |A_2 U|^2 = |\partial_{\kappa_z} U|^2 + |\partial_{\kappa_z} U|^2 - |A_3 U|^2 \text{ for all } U \in C^1(\mathbb{R}^3 \times S^2). \]

Ideally \( m = 1 \) since then the approximation is exact. For relevant parameter settings we indeed have \( m \approx 1 \) up to 5-percent \( \ell_\infty \)-errors as can be seen in Figure 14.

**11 Pseudo Linear Scale Spaces on** \( \mathbb{R}^3 \times S^2 \)

So far we have considered anisotropic diffusions aligned with fibers and erosions orthogonal to the fibers. As these two types of left-invariant evolutions are supposed to be alternated,

\[ \Phi_t^{G = \text{diag}(g_{11}, g_{11}, g_{44}, g_{44}, 0) \text{ } e^{cQ^0 = \text{diag}(D_{11}, D_{11}, D_{44}, D_{44}, 0)} \text{ } x = y \text{ } \text{or} \text{ } \Phi_t^{G = \text{diag}(g_{11}, g_{11}, g_{44}, g_{44}, 0)}} \]

37
where \( g^{ij} \) are the components of the inverse metric, which in case of a diagonal metric tensor simply reads \( g^{ii} = g_{ii}^{-1} = D_{ii} \), like in (52) where \( D^{ij} \gg D^{11} \) and where \( \Phi_t \) denotes the viscosity solution operator \( U \mapsto W(\cdot, \cdot, t) \) for the erosion Hamilton-Jacobi equation (52). The natural question arises is there a single evolution process that combines erosion/dilation and diffusion. Moreover, a from a practical point of view quite satisfactory alternative to visually sharpen distributions on positions and orientations is to apply monotonic greyvalue transformations (instead of an erosion) such as for example the power operator \( \tilde{\chi}_p \)

\[
(\tilde{\chi}_p(U))(y, n) = (U(y, n))^p,
\]

where \( p \geq 1 \), where we also recall the drawback illustrated in Figure 4 Conjugation of the diffusion operator with a monotonically increasing grey-value transformation \( \chi : \mathbb{R}^+ \rightarrow \mathbb{R}^+ \)

\[
\chi^{-1} \circ e^{tQ^{\beta, \gamma}(\nabla)} \circ \chi
\]

is related to simultaneous erosion and diffusion. For a specific choice of grey-value transformations this is indeed the case we will show next, where we extend the theory for pseudo linear scale space representations of greyscale images [35] to DW-MRI (HARDI and DTI).

Next we derive the operator \( \chi^{-1} \circ e^{tQ^{\beta, \gamma}(\nabla)} \circ \chi \) more explicitly using the chain-law for differentiation:

\[
\begin{align*}
\mathcal{A}_i(\chi(V(\cdot, \cdot, t))) &= \chi'(V(\cdot, \cdot, t)) \mathcal{A}_i(V(\cdot, \cdot, t)), \\
\partial_t \chi(V(\cdot, \cdot, t)) &= \chi'(V(\cdot, \cdot, t)) \partial_t V(\cdot, \cdot, t), \\
\mathcal{A}_i \mathcal{A}_j(\chi(V(\cdot, \cdot, t))) &= \chi''(V(\cdot, \cdot, t)) \mathcal{A}_i(V(\cdot, \cdot, t)) \mathcal{A}_j(V(\cdot, \cdot, t)) + \chi'(V(\cdot, \cdot, t)) \mathcal{A}_i \mathcal{A}_j(V(\cdot, \cdot, t)).
\end{align*}
\]

Consequently, if we set \( W(\cdot, \cdot, t) = \chi(V(\cdot, \cdot, t)) \Leftrightarrow V(\cdot, \cdot, t) = \chi^{-1}(W(\cdot, \cdot, t)) \) and

\[
W(\cdot, \cdot, t) = e^{tQ^{\beta, \gamma}(\nabla)} W(\cdot, \cdot, 0),
\]

see Figure 15, then \( V \) satisfies

\[
\begin{cases}
\partial_t V(y, n, t) = \sum_{i=1}^{5} D^{ij}_{\chi(V(y, n), t)} (\mathcal{A}_i V(y, n, t))^2, \\
V(y, n, 0) = \chi^{-1}(U(y, n)).
\end{cases}
\]

(94)

where \( \tilde{\mu}(V(y, n, t)) = \frac{\chi''(\chi(V(y, n, t)))}{\chi'(\chi(V(y, n, t)))} \). So if we set \( \tilde{\mu}(V(y, n, t)) = C \) constant we achieved that (93) coincides with a simultaneous erosion/dilation and diffusion with

\[
G^{-1} = \sum_{i,j=1}^{5} g^{ij} \mathcal{A}_i \otimes \mathcal{A}_j = \sum_{i,j=1}^{5} D^{ij}_{\chi(V(y, n, t))} \mathcal{A}_i \otimes \mathcal{A}_j.
\]

38
Figure 15: The commutative diagram of simultaneous left-invariant dilation and diffusion along the fibers \((D_{33} \gg D_{11})\) given by Eq. (94) with \(\tilde{\mu}(V(y,n,t)) = C\) illustrates that conjugation of specific grey-value transformations (96) with left-invariant diffusion is equivalent.

\[
\begin{array}{ccc}
U(\cdot, \cdot) & \xrightarrow{e^{t D_{33}a(\nabla)}} & W(\cdot, \cdot, t) \\
\chi^{-1} & & \chi \\
V(\cdot, \cdot, 0) & \xrightarrow{\text{dilation & diffusion}} & V(\cdot, \cdot, t)
\end{array}
\]

\[
\text{Figure 16: Left: Graphs of the grey-value transformations, Eq. (96), that are solutions } \chi_C : [0, 1] \to [0, 1] \text{ of Eq. (95), for } C = \{-8, -4, -2, -1, 0, 1, 2, 4, 8\} \text{ (depicted from left to right). The concave solutions correspond to diffusion and erosion whereas the convex solutions yield convection and diffusion. Right: Graphs of the convex } \chi_C \text{ of Eq. (95) depicted together with their inverse } \chi_C^{-1} \text{, Eq (97), for } C = \{-8, -4, -2, -1\}.
\]

This means we have to solve the following ODE-system

\[
\begin{align*}
\chi''(I) - C \chi'(I) &= 0, & I \in [0, 1], \\
\chi(0) &= 0 \text{ and } \chi(1) = 1,
\end{align*}
\]

where \(I \in [0, 1]\) stands for intensity where in particular we set \(I := \frac{V(y,n,0) - \min_{y,n} V(y,n,0)}{\max_{y,n} V(y,n,0) - \min_{y,n} V(y,n,0)}(y,n) \in \mathbb{R}^3 \rtimes S^2\).

The unique solutions of (95) are given by

\[
\chi_C(I) = \begin{cases} 
\frac{e^{CI} - 1}{CI} & \text{if } C \neq 0 \\
I & \text{if } C = 0 
\end{cases}
\]

so that \(V(y,n,t)\) is the solution of an evolution (44) where the generator is a weighted sum of a diffusion and erosion/dilation operator. The inverse of \(\chi\) is given by

\[
\chi_C^{-1}(I) = \begin{cases} 
\frac{1}{C} \ln(1 + (e^C - 1)I) & \text{if } C \neq 0 \\
I & \text{if } C = 0
\end{cases}
\]

The drawback of this intriguing correspondence, is that our diffusions primarily take place along the fibers, whereas our erosions take place orthogonal to the fibers. Therefore, at this point the correspondence between pseudolinear scale spaces and hypo-elliptic diffusion conjugated with \(\xi\) is primarily useful for simultaneous dilation and diffusion along the fibers\(^7\), i.e. the case

\[
D = \text{diag}\{0, 0, D_{11}, D_{22}, D_{33}, 0\} \text{ and } C > 0.
\]

\(^7\)In general one does not want to erode and diffuse in the same direction.
Remark 4 Finally, for \(C \approx 2\) the operator in Eq. (93) is close to the operators applied in Figure 1 and Figure 2 on DTI and HARDI data of the brain. The difference though is that (93) conjugates a diffusion operator with greyvalue transformations, whereas in Figure 1 and 2 we applied \(\chi_p \circ e^{Q^{p,x}(\nabla)} \circ \chi_p\) with \(p = 2\).

### 12 Implementation of the Left-Invariant Derivatives and \(\mathbb{R}^3 \rtimes S^2\)-Evolutions

In our implementations we do not use the two charts (among which the Euler-angles parametrization) of \(S^2\) because this would involve cumbersome and expensive bookkeeping of mapping the coordinates from one chart to the other (which becomes necessary each time the singularities (14) and (17) are reached). Instead we recall that the left-invariant vector fields on HARDI-orientation scores \(\tilde{U} : SE(3) \to \mathbb{R}\), which by definition (recall Definition 3) automatically satisfy

\[
\tilde{U}(RR_{e_n,a}) = \tilde{U}(R),
\]

are constructed by the derivative of the right-regular representation

\[
A_i \tilde{U}(g) = (dR(A_i)\tilde{U})(g) = \lim_{h \to 0} \frac{\tilde{U}(g e^{h A_i}) - \tilde{U}(g)}{h} = \lim_{h \to 0} \frac{\tilde{U}(g e^{-h A_i}) - \tilde{U}(g)}{2h},
\]

where in the numerics we can take finite step-sizes in the righthand side. Now in order to avoid a redundant computation we can also avoid taking the de-tour via HARDI-orientation scores and actually work with the left-invariant vector fields on the HARDI data itself. To this end we need the consistent right-action \(\mathcal{R}\) of \(SE(3)\) acting on the space of HARDI images \(L_2(\mathbb{R}^3)\times S^2\). To construct this consistent right-action we formally define \(S : L_2(\mathbb{R}^3)\times S^2) \to H\), where \(H\) denotes the space of HARDI-orientation scores, that equals the space of quadratic integrable functions on the group \(SE(3)\) which are \(\sigma\)-right-invariant, i.e. satisfying (98) by

\[
(SU)(\mathbf{x}, R) = \tilde{U}(\mathbf{x}, R) = U(\mathbf{x}, R e_n).
\]

This mapping is injective and its left-inverse is given by \((S^{-1})\tilde{U}(\mathbf{x}, n) = \tilde{U}(\mathbf{x}, R_n)\), where again \(R_n \in SO(3)\) is some rotation such that \(R_n e_n = n\). Now the consistent right-action \(\mathcal{R} : SE(3) \to B(L_2(\mathbb{R}^3)\times S^2)\), where \(B(L_2(\mathbb{R}^3)\times S^2)\) stands for all bounded linear operators on the space of HARDI images, is (almost everywhere) given by

\[
\mathcal{R}_{(x,R)}(U)(\mathbf{y}, \mathbf{n}) = (S^{-1} \circ R_{(x,R)} \circ SU)(\mathbf{y}, \mathbf{n}) = U(R_n \mathbf{x} + \mathbf{y}, R_n R e_n).
\]

This yields the left-invariant vector fields (directly) on sufficiently smooth HARDI images:

\[
A_i U(\mathbf{y}, \mathbf{n}) = (d\mathcal{R}(A_i)U)(\mathbf{y}, \mathbf{n}) = \lim_{h \to 0} \frac{\mathcal{R}_{(x,R)}(A_i U(\mathbf{y}, \mathbf{n} - h R e_n, n) - U(\mathbf{y}, \mathbf{n}))}{h} = \lim_{h \to 0} \frac{\mathcal{R}_{(x,R)}(U(\mathbf{y}, \mathbf{n} - h R e_n, n)) - \mathcal{R}_{(x,R)}(U(\mathbf{y}, \mathbf{n})))}{2h}.
\]

Now in our algorithms we take finite step-sizes and elementary computations (using the exponent (71)) yield the following simple expressions for the discrete left-invariant vector fields, for respectively central,

\[
A_1 U(\mathbf{y}, \mathbf{n}) \approx A_1^c U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} + h R e_n, \mathbf{n}) - U(\mathbf{y} - h R e_n, \mathbf{n})}{2h},
\]

\[
A_2 U(\mathbf{y}, \mathbf{n}) \approx A_2^c U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} + h R e_n, \mathbf{n}) - U(\mathbf{y} - h R e_n, \mathbf{n})}{2h},
\]

\[
A_3 U(\mathbf{y}, \mathbf{n}) \approx A_3^c U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} + h R e_n, \mathbf{n}) - U(\mathbf{y} - h R e_n, \mathbf{n})}{2h},
\]

forward,

\[
A_1 U(\mathbf{y}, \mathbf{n}) \approx A_1^f U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} - h R e_n, \mathbf{n}) - U(\mathbf{y} + h R e_n, \mathbf{n})}{h},
\]

\[
A_2 U(\mathbf{y}, \mathbf{n}) \approx A_2^f U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} - h R e_n, \mathbf{n}) - U(\mathbf{y} + h R e_n, \mathbf{n})}{h},
\]

\[
A_3 U(\mathbf{y}, \mathbf{n}) \approx A_3^f U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} - h R e_n, \mathbf{n}) - U(\mathbf{y} + h R e_n, \mathbf{n})}{h},
\]

and backward,

\[
A_1 U(\mathbf{y}, \mathbf{n}) \approx A_1^b U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} + h R e_n, \mathbf{n}) - U(\mathbf{y} - h R e_n, \mathbf{n})}{h},
\]

\[
A_2 U(\mathbf{y}, \mathbf{n}) \approx A_2^b U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} + h R e_n, \mathbf{n}) - U(\mathbf{y} - h R e_n, \mathbf{n})}{h},
\]

\[
A_3 U(\mathbf{y}, \mathbf{n}) \approx A_3^b U(\mathbf{y}, \mathbf{n}) := \frac{U(\mathbf{y} + h R e_n, \mathbf{n}) - U(\mathbf{y} - h R e_n, \mathbf{n})}{h}.
\]
left-invariant finite differences. The left-invariant vector fields \( \{A_1, A_2, A_3, A_4\} \) clearly depend on the choice of \( R_n \in SO(3) \) which maps \( R_n e_z = n \). Now functions in the space \( H \) are \( \alpha \)-right invariant, so thereby we may assume that \( R \) can be written as \( R = R_{\alpha \gamma \eta} R_{\delta \lambda} \), now if we choose \( R_n \) again such that \( R_{n(\alpha \gamma \eta)} R_{\delta \lambda} = R_{\alpha \gamma \eta} R_{\delta \lambda} \alpha = \alpha_0 = 0 \) then we take consistent sections in \( SO(3)/SO(2) \) and we get full invertibility \( S^{-1} \circ S = S \circ S^{-1} = I \).

Our evolution schemes, however, the choice of representant \( R_n \) is irrelevant, because they are well-defined on the quotient \( \mathbb{R}^3 \times S^2 = SE(3)/\langle \{0\} \times SO(2) \rangle \).

In the computation of (99) one would have liked to work with discrete subgroups of \( SO(3) \) acting on \( S^2 \) in order to avoid interpolations, but unfortunately the platonic solid with the largest amount of vertices (only 20) is the dodecahedron and the platonic solid with the largest amount of faces (again only 20) is the icosahedron. Nevertheless, we would like to sample the 2-sphere such that the distance between sampling points should be as equal as possible and simultaneously the area around each sample point should be as equal as possible. Therefore we follow the common approach by regular triangulations (i.e. each triangle is regularly divided into \( (o + 1)^2 \) triangles) of the icosahedron, followed by a projection on the sphere. This leads to \( N_\alpha = 2 + 10(o + 1)^2 \) vertices. We typically considered \( o = 1, 2, 3 \), for further motivation regarding uniform spherical sampling, see [38, ch.7.8.1].

For the required interpolations to compute (99) within our spherical sampling there are two simple options. Either one uses a triangular interpolation of using the three closest sampling points, or one uses a discrete spherical harmonic interpolation. The disadvantage of the first and simplest approach is that it introduces additional blurring, whereas the second approach can lead to overshoots and undershoots. In both cases it is for computational efficiency advisable to pre-compute the interpolation matrix, cf. [20, ch:2.1], [40, p.193]. See Appendix F.

### 12.1 Finite difference schemes for diffusion and pseudo-linear scale spaces on \( \mathbb{R}^3 \times S^2 \)

The linear diffusion system on \( \mathbb{R}^3 \times S^2 \) can be rewritten as

\[
\begin{cases}
\partial_t W(y, n, t) = (D_{11}((A_1)_n^2 + (A_2)_n^2) + D_{33}(A_3)_n^2 + D_{44} \Delta_{S^2}) W(y, n, t) \\
W(y, n, 0) = U(y, n),
\end{cases}
\]

This system is the Fokker-Planck equation of horizontal Brownian motion on \( \mathbb{R}^3 \times S^2 \) if \( D_{11} = 0 \). Spatially, we take second order centered finite differences for \( (A_1)_n^2, (A_2)_n^2 \) and \( (A_3)_n^2 \), i.e. we applied the discrete operators in the righthand side of (99) twice (where we replaced \( 2h \mapsto h \) to ensure direct-neighbors interaction), so we have

\[
((A_3)_n^2 W(y, n, t)) \approx \frac{W(y + h R_n e_z, n, t) - 2 W(y, n, t) + W(y - h R_n e_z, n, t)}{h^2},
\]

For each \( q \in \mathbb{N} \cup \{0\} \), we define the vector \( w^q = (w_{\eta,k}^q)_{k=1 \ldots N_\eta, \eta \in \mathcal{I}} \in \mathbb{R}^{N_\eta N_\eta} \), where \( k \) enumerates the number of samples on the sphere, where \( y \) enumerates the samples on the discrete spatial grid \( \mathcal{I} = \{1, \ldots, N\} \times \{1, \ldots, N\} \times \{1, \ldots, N\} \) and where \( q \) enumerates the discrete time frames. Rewrite (103) and (102) in vector form using Euler-forward first order approximation in time:

\[
w^{q+1} = (I - \Delta t(J_{Sz} + J_{Sz}))w^q,
\]

where \( J_{Sz} \in \mathbb{R}^{N_\eta N_\eta \times N_\eta N_\eta} \) denotes the angular increments block-matrix and where \( J_{Sz} \in \mathbb{R}^{N_\eta N_\eta \times N_\eta N_\eta} \) denotes the spatial increments block-matrix.

#### 12.1.1 Angular increments block-matrix

The angular increments block-matrix equals in the basic (more practical) approach, cf.[20], of (tri-)linear spherical interpolation

\[
J_{Sz} = h_a^{-2} D_{44}(B_4 + B_5),
\]
with angular stepsize $h_a > 0$ and with $B_4$ and $B_5$ are matrices with 2 on the diagonal and where for each column the of off-diagonal elements is also equal to 2. See Appendix F, Eq. (163), for details.

In the more complicated discrete spherical harmonic transform interpolation approach, cf. [33, Ch.7] the angular increments block-matrix is given by

$$J_{S^2} = I \otimes B^{44} \Lambda^{-1} M^T Q M A \in \mathbb{R}^{(N^3 N_o) \times (N^3 N_o)}, \quad \text{with} \quad Q = \text{diag}_{j=1, \ldots, N_{SH}} \{ l(j)(l(j) + 1)e^{-t_{\text{reg}}l(j)(l(j) + 1)} \},$$

(105)

with regularization parameter $t_{\text{reg}} > 0$ and where $N_{SH}$ represents the number of spherical harmonics and with $n_{SH} \times N_o$-matrix

$$M = [M_k^j] = \left[ \frac{1}{\sqrt{C}} Y_{m(j)}^l(n_k) \right], \quad \text{with} \quad l(j) = \lfloor \sqrt{j - 1} \rfloor \text{ and } m(j) = j - (l(j))^2 - l(j) - 1$$

with $C = \sum_{j=1}^{n_{SH}} |Y_{m(j)}^l(0, 0)|^2$ and where the diagonal matrix $A = \text{diag}\{ \delta_{S^2}(n_1), \ldots, \delta_{S^2}(n_{N_o}) \}$ contains discrete surface measures $\delta_{S^2}(n_k)$ (for spherical sampling by means of higher order tessellations of the icosahedron) given by

$$\delta_{S^2}(n_k) = \frac{1}{6} \sum_{i \neq k, j \neq k; i \neq j, i \sim j \sim k} A(n_i, n_j, n_k), \quad (106)$$

where $i \sim j$ means that $n_i$ and $n_j$ are part of a locally smallest triangle in the tessellation and where the surface measure of the spherical projection of such a triangle is given by

$$A(n_i, n_j, n_k) = 4 \arctan(\sqrt{\tan(s_{ijk}/2) \tan((s_{ijk} - s_{ij})/2) \tan((s_{ijk} - s_{ik})/2) \tan((s_{ijk} - s_{jk})/2)}),$$

with $s_{ijk} = \frac{1}{2}(s_{ij} + s_{ik} + s_{jk})$ and $s_{ij} = \arccos(n_i \cdot n_j)$.

12.1.2 Spatial increments matrix

In both approaches the spatial increments block matrix equals $J_{\mathbb{R}^3}$ given by Eq. (163) in Appendix F.

12.1.3 Stability bounds on the step-size

We have guaranteed stability iff

$$\|I - \Delta t(J_{S^2} + J_{\mathbb{R}^3})\| = \sup_{\|w\|=1} \| (I - \Delta t(J_{S^2} + J_{\mathbb{R}^3})w \| < 1,$$

which is by $I - \Delta t(J_{S^2} + J_{\mathbb{R}^3}) = (\nu I - \Delta t J_{\mathbb{R}^3}) + ((1 - \nu)I - \Delta t J_{S^2})$, with $\nu \in (0, 1)$, the case if

$$\|I - \frac{\Delta t}{\nu} J_{\mathbb{R}^3}\| < 1 \text{ and } \|I - \frac{\Delta t}{1 - \nu} J_{S^2}\| < 1 \Rightarrow \| (\nu I - \Delta t J_{\mathbb{R}^3}) + ((1 - \nu)I - \Delta t J_{S^2})\| < \nu + (1 - \nu) = 1. \quad (107)$$

Sufficient (and sharp) conditions for the first inequality are obtained by means of the Gerschgorin Theorem [42] :

$$\Delta t \leq \frac{\nu h^2}{4D^{11} + 2D^{33}}, \quad (108)$$

Application of the Gerschgorin Theorem [42] on the second equality gives after optimization over $\nu$, the following global guaranteed-stability bound

$$\Delta t \leq \frac{1}{4D^{11} + 2D^{33} + \frac{4D^{11}}{h^2}}. \quad (109)$$
Next we address two minor issues that arise when implementing the convolution algorithms \([33, \text{ch:8.2}]\) and \([59]\): morphological convolutions. In the linear interpolation case and erosion kernels are mainly supported near the \(x, y, z\) plane, but the efficiency principles are easily carried over to the \(S^2\)-convolutions with analytic Green’s functions for diffusion. Basically, the algebra \((+, \cdot)\) is to be replaced by respectively the \((\max, +)\) and \((\min, +)\)-algebra. So the results on fast efficient computation, using lookup-tables and/or parallelization cf. \([59]\), apply also to the spherical sampling, i.e. one must solve the central difference determines whether a forward or central difference is taken.

\[ W(y, n, t + \Delta t) = W(y, n) + \frac{\Delta t}{D^{11}} \left( D^{11} \left( a^{-1}(y, n) U(y, n) - U(y-h R_n e_x, n) + a^{+1}(y, n) U(y+h R_n e_x, n) - U(y, n) \right)^2 \right) \]

where the functions \(a^{-1}, a^{+1}\) are given by

\[
\begin{align*}
    a^{-1}(y, n) &= \max \left\{ 0, U(y-h R_n e_x, n) - U(y-h R_n e_x, n) \right\}, \\
    a^{+1}(y, n) &= \min \left\{ 0, U(y-h R_n e_x, n) - U(y-h R_n e_x, n) \right\}, \\
    a^{-2}(y, n) &= \max \left\{ 0, U(y-h R_n e_y, n) - U(y-h R_n e_y, n) \right\}, \\
    a^{+2}(y, n) &= \min \left\{ 0, U(y-h R_n e_y, n) - U(y-h R_n e_y, n) \right\}, \\
    a^{+4}(y, n) &= \max \left\{ 0, U(y, R_n R_{e_y} e_z) - U(y, R_n R_{e_y} e_z) \right\}, \\
    a^{-4}(y, n) &= \min \left\{ 0, U(y, R_n R_{e_y} e_z) - U(y, R_n R_{e_y} e_z) \right\}, \\
    a^{+5}(y, n) &= \min \left\{ 0, U(y, R_n R_{e_y} e_z) - U(y, R_n R_{e_y} e_z) \right\}.
\end{align*}
\]

1. In the implementation with analytical kernels expressed in the second chart, such as \((83)\) one needs to extract the second chart Euler angles \((\beta, \gamma)\) from each normal \(n\) in the spherical sampling, i.e. one must solve \(n(\beta, \gamma) = n\). The solutions are

\[
(\beta, \gamma) = (\text{sign}(n_1) \arccos(\text{sign}(n_2 \sqrt{n_2^2 + n_3^2})), -\text{sign}(n_3) \arcsin \left( \frac{n_2}{\sqrt{n_2^2 + n_3^2}} \right))
\]
master thesis. Regarding discretization of (113) in the finite difference schemes of Subsection 12.1 we propose the replacement sets a soft-threshold on the diffusion in we used (113) where both the diffusion equation and the mapping in the generator of the left-invariant diffusion (44) (where a propagation by hypo-elliptic diffusion, one expects a large be small, whereas in the transition areas between ventricles and white matter, where one needs to block the fiber and nonlinear. In the experiments, however we extended the standard approach by PeronaMalik [57] to here could also choose to adapt the diffusivity by the original DW-MRI data diffusion equation itself is linear, whereas the mapping \( U \mapsto \Phi_t(U) := W(\cdot, t) \) in Eq. (13) included is well-posed and nonlinear. In the experiments, however we extended the standard approach by PeronaMalik [57] to \( \mathbb{R}^3 \times S^2 \) and we used (13) where both the diffusion equation and the mapping \( U \mapsto W(\cdot, t) \) are nonlinear. The idea is simple: the replacement sets a soft-threshold on the diffusion in \( A_3 \)-direction, at fiber locations one expects \( |A_3U(y, n)| \) to be small, whereas in the transition areas between ventricles and white matter, where one needs to block the fiber propagation by hypo-elliptic diffusion, one expects a large \( |A_3U(y, n)| \). For further details see the second author's master thesis [20]. Regarding discretization of (113) in the finite difference schemes of Subsection 12.1 we propose

\[
(A_3(D^{33} e^{-\frac{|A_3W(\cdot, t)|^2}{\kappa^2}} A_3W(\cdot, t))) (y, n) \approx \frac{\tilde{D}^{33} (y + \frac{1}{2} h, n, t) \cdot A_3^3W(y + \frac{1}{2} h, n, t) - \tilde{D}^{33} (y - \frac{1}{2} h, n, t) \cdot A_3^3W(y - \frac{1}{2} h, n, t)}{h}
\]

where \( h \) is the spatial stepsize and where \( h = hR_n e_z \) for notational convenience and where

\[
\tilde{D}^{33}(y, n, t) = D^{33} e^{- \frac{\max\{|A_3^3W(\cdot, t)|, |A_3^3W(\cdot, t)|\}}{\kappa}}.
\]

and where we recall Eq. (99), Eq. (100) and Eq. (101) for central, forward and backward finite differences.

13 Adaptive, Left-Invariant Diffusions on HARDI images

13.1 Scalar Valued Adaptive Conductivity

In order to avoid mutual influence of anisotropic regions (areas with fibers) and isotropic regions (ventricles) one can replace the constant diffusivity/conductivity \( D^{33} \) by

\[
D^{33} A_3 A_3 \mapsto D^{33} \circ e^{-\frac{|A_3W(\cdot, t)|^2}{\kappa^2}} \circ A_3,
\]

in the generator of the left-invariant diffusion (44) (where \( a = 0 \) and \( D = \text{diag}\{0, 0, D^{33}, 0, 0\} \)). This now yields the following hypoelliptic diffusion system

\[
\frac{\partial W(y, n, t)}{\partial t} = D^{33} A_3|_{y, n}(e^{-\frac{|A_3W(y, n, t)|^2}{\kappa^2}} A_3W)(y, n, t),
\]

(113)

Here could also choose to adapt the diffusivity by the original DW-MRI data \( U : \mathbb{R}^3 \times S^2 \to \mathbb{R}^+ \) at time 0, so that the diffusion equation itself is linear, whereas the mapping \( U \mapsto \Phi_t(U) := W(\cdot, t) \) in Eq. (13) included is well-posed and nonlinear. In the experiments, however we extended the standard approach by PeronaMalik [57] to \( \mathbb{R}^3 \times S^2 \) and we used (13) where both the diffusion equation and the mapping \( U \mapsto W(\cdot, t) \) are nonlinear. The idea is simple: the replacement sets a soft-threshold on the diffusion in \( A_3 \)-direction, at fiber locations one expects \( |A_3U(y, n)| \) to be small, whereas in the transition areas between ventricles and white matter, where one needs to block the fiber propagation by hypo-elliptic diffusion, one expects a large \( |A_3U(y, n)| \). For further details see the second author’s master thesis [20]. Regarding discretization of (113) in the finite difference schemes of Subsection 12.1 we propose

\[
(A_3(D^{33} e^{-\frac{|A_3W(\cdot, t)|^2}{\kappa^2}} A_3W(\cdot, t))) (y, n) \approx \frac{\tilde{D}^{33} (y + \frac{1}{2} h, n, t) \cdot A_3^3W(y + \frac{1}{2} h, n, t) - \tilde{D}^{33} (y - \frac{1}{2} h, n, t) \cdot A_3^3W(y - \frac{1}{2} h, n, t)}{h}
\]

where \( h \) is the spatial stepsize and where \( h = hR_n e_z \) for notational convenience and where

\[
\tilde{D}^{33}(y, n, t) = D^{33} e^{- \frac{\max\{|A_3^3W(\cdot, t)|, |A_3^3W(\cdot, t)|\}}{\kappa}}.
\]
13.2 Tensor-valued adaptive conductivity

For details see [33] and [25, Ch:9], where we generalized the results in [30, 39]. Current implementations do not produce the expected results. Here the following problems arise. Firstly, the logarithm and exponential curves in Section 9.1 are not well-defined on the quotient \( \mathbb{R}^3 \rtimes S^2 \) and we need to take an appropriate section through the partition of cosets in \( \mathbb{R}^3 \rtimes S^2 \). Secondly, the \( 6 \times 6 \) Hessian in [25, Eq.103,Ch:9] has a nilspace in \( A_6 \)-direction.

14 Experiments and Evaluation

First we provide a chronological evaluation of the experiments depicted in various Figures so far.

In Figure 2 and Figure 3 one can find experiments of \( \mathbb{R}^3 \times S^2 \)-convolution implementations of hypo-elliptic diffusion ("contour enhancement", cf. Figure 10), Eq. (49), using the analytic approximation of the Green’s function Eq. (83). Typically, these \( \mathbb{R}^3 \times S^2 \)-convolution kernel operators propagate fibers slightly better at crossings, as they do not suffer from numerical blur (spherical interpolation) in finite difference schemes explained in Section 12.1. Compare Figure 2 to Figure 5, where the same type of fiber crossings of the corona radiata and corpus callosum occur. Here we note that all methods in Figure 5 have been evaluated by finite difference schemes, based on linear spherical interpolation, with sufficiently small time steps \( \Delta t \), recall Eq. (109) using 162 spherical samples from a higher order tessellation of the icosahedron. In Figure 5 the visually most appealing results are obtained by a single concatenation of diffusion and erosion. Then in Figure 4 we have experimentally illustrated the short-coming of sharpening the data by means of squaring in comparison to the erosions, Eq. (52). Experiments of the latter evolution, implemented by the upwind finite difference method described in Section 12.2, has been illustrated for various parameter settings in Figure 8 (also in Figure 5). The possibilities of a further modification, where erosion is locally adapted to the data, can be found in Figure 9. Then in Figure 10 and Figure 11 we have depicted the Green’s functions of the (iterated) direction process (hypo-elliptic convection and diffusion) that we applied in a fiber completion experiment in Figure 12.

The experiments in Figure 5 (implemented in Mathematica 7) take place on volumetric DTI-data-sets \( 104 \times 104 \times 10 \) where we applied (2) using 162 samples on the sphere (tessellation icosahedron). In Figure 17 we illustrate the enhancement and eroding effect in 3D, of the same experiments as in Figure 5 where we took two different viewpoints on a larger 3D-part of the total data-set.

In the remaining subsections we will consider some further experiments on respectively diffusion, erosion and pseudo-linear scale spaces.

14.1 Further experiments diffusions

In Figure 18 we have applied both linear and nonlinear diffusion on an noisy artificial data set which both contains an anisotropic part (modeling neural fibers) and containing a large isotropic part (modeling ventricles, compare to Fig. 5). When applying linear diffusion on the data-set the isotropic part propagates and destroys the fiber structure in the anisotropic part, when applying nonlinear diffusion with the same parameter settings, but now with \( D^{33} = e^{-\frac{|A_3(y,n)|^2}{K^2}} \) and suitable choice of \( K > 0 \) one turns of the propagation (diffusion-flow) through the boundary between isotropic and non-isotropic areas where \( (y,n) \mapsto |A_3(y,n)|^2 \) is relatively high. Consequently, both the fiber-part and the ventricle part are both appropriately diffused without too much influence on each other, yielding both smooth/aligned fibers and smooth isotropic glyphs.
Figure 17: Same experiments as in Figure 5, but now visualized with several slices in 3D. First row: Input DTI-data set. Second row: Output squared linear diffusion on squared data-set. Third row: Output erosion applied to the diffused dataset depicted in the second row. For parameter settings, see Figure 5.

Figure 18: Adaptive diffusivity/conductivity based on the data, Section 13.1. Top row: Artificial $15 \times 15 \times 15 \times 162$-input data that is a sum of a noisy fiber part and a noisy isotropic part. For the sake of visualization we depicted these parts separately. Bottom row: Output of just linear diffusion (without greyvalue transformations, nor Eq. (4)), $t = 1$, $D_{33}^{y^1} = 1$, $D_{44}^{y^1} = 0.04$. Output nonlinear diffusion with $t = 1$, $D_{33}^{y^1} = 1$, $D_{14}^{y^1} = 0.015$, $K = 0.05$, $\Delta t = 0.01$. 

\[
\text{Input } U = U_1 + U_2
\]

\[
\text{Output } \Phi_t(U) \text{ linear diffusion}
\]

\[
\text{Output } \Phi_t(U) \text{ nonlinear diffusion}
\]
14.2 Further experiments erosions

Erosions yield a geometrical alternative to more ad-hoc data-sharpening by squaring, see Fig:4 for a basic illustration. We compared angular erosions for several values of $\eta \in [0, 1]$, in Figure 19, where we fixed $D^{44} = 0.4$, $D^{11} = 0$ and $t = 0.4$ in Eq. (52). Typically, for $\eta$ close to a half the structure elements are more flat, Eq. (89) and Eq. (90) leading to a more radical erosion effect if time is fixed. Note that this difference is also due to the fact that $D^{11}$ in Eq. (52) has physical dimension $\frac{\text{Intensity}}{\text{Length}^2 \text{Time}}$ and $D^{44}$ has physical dimension $\frac{\text{Intensity}}{\text{Time}^2}$. We have implemented two algorithms for erosion, by morphological convolution in $\mathbb{R}^3 \times S^2$ erosions Eq. (39) with analytical kernel approximations Eq. (89) and finite difference upwind schemes with stepsize $t > 0$. A drawback of the morphological convolutions is that it typically requires high sampling on the sphere, as can be seen in Figure 20, whereas the finite difference schemes also work out well for low sampling rates (in the experiments on real medical data sets in 5 we used a 162-point tessellation of the icosahedron). Nevertheless, for high sampling on the sphere the analytical kernel implementations were close to the numerical finite difference schemes and apparently our analytical approximation Eq. (90) approximates the propagation of balls in $\mathbb{R}^3 \times S^2$ close enough for reasonable parameter-settings in practice. Upwind finite difference schemes are better suited for low sampling rates on the sphere, but for such sampling rates they do involve inevitable numerical blur due to spherical grid interpolations. Typically, erosions should be applied to strongly smoothed data as it enhances local extrema. In Figure 5, lower left corner one can see the result on a DTI-data set containing fibers of the corpus callosum and corona radiata, where the effect of both spatial erosion (glyphs in the middle of a “fiber bundle” are larger than the glyphs at the boundary) and angular erosion glyphs are much sharper so that it is easier to visually track the smoothly varying fibers in the output dataset. Typically, as can be seen in Fig. 5, applying first diffusion and then erosion is stable with respect to the parameter settings and produces visually more appealing sharper results then simultaneous diffusion and dilation in pseudo-linear scale spaces.

14.3 Further experiments pseudo-linear scale spaces

Pseudo-linear scale spaces, Eq.94 combine diffusion and dilation along fibers in a single evolution. The drawback is a relatively sensitive parameter $C > 0$ that balances infinitesimally between dilation and diffusion. In Figure 21 we applied some experiments where we kept parameters fixed except for $C > 0$. The generator of a pseudo-linear scale space consists of a diffusion generator plus $C$ times an erosion generator and indeed for $C = 4$ we see more elongated
Figure 21: Pseudo-linear scale space on $\mathbb{R}^3 \times S^2$ applied on the initial DTI-dataset in Figure 5. $t = D^{33} = 1$, $D^{44} = 0.04$, $\Delta t = 0.01$, top: $C = 2$, bottom: $C = 4$.

glyphs and more apparent crossings than for the case $C = 2$.

15 Conclusion

For the purpose of tractography detection and visualization of biological fibers, Diffusion-Weighted MRI-images, such as DTI and HARDI, should be enhanced such that fiber junctions are maintained, while reducing high frequency noise in the joint domain $\mathbb{R}^3 \times S^2$ of positions and orientations. Therefore we have considered diffusions and Hamilton-Jacobi equations on DW-MRI HARDI and DTI induced by fundamental stochastic processes on $\mathbb{R}^3 \times S^2$ embedded in the group manifold $SE(3)$ of 3D-rigid body motions. In order to achieve rotation and translation covariance, processing must be left-invariant. We have classified all left-invariant linear and morphological scale spaces on DW-MRI. This classifications yield novel approaches, that in contrast to the existing methods, employ fiber extensions simultaneously over positions and orientations, while preserving crossings and/or bifurcations. Application on DTI creates fiber-crossings by extrapolation, comparable to HARDI, allowing to reduce the number of scanning directions, whereas applying the same method to HARDI removes spurious non-aligned crossings. In order to sharpen the DW-MRI images, we apply morphological scale spaces (Hamilton-Jacobi equations) related to probabilistic cost-processes on $\mathbb{R}^3 \times S^2$. Moreover, we provide pseudo-linear scale spaces combining morphological scale spaces and linear scale spaces in a single evolution. All evolutions can be implemented by stable, left-invariant finite difference methods, or by convolution with analytic kernels. For example, we have shown by extending existing results on $\mathbb{R}^n$ (and recently on the Heisenberg group to $SE(3)$, cf.[52]), that morphological $\mathbb{R}^3 \times S^2$-convolutions are the unique viscosity solutions of Hamilton-Jacobi equations on $\mathbb{R}^3 \times S^2$ and moreover we have provided analytical approximations of the morphological kernels (Green’s functions). Finally, we have extended anisotropic linear diffusions systems on $\mathbb{R}^3 \times S^2$ to data-adaptive diffusion systems of Perona Malik type that are useful to avoid undesired interaction between more isotropic regions (at the neural fibers) and less isotropic regions (at the ventricles).
In future work we aim to extend our differential geometrical approach on $\mathbb{R}^3 \times S^2$ to the actual tracking of fibers.

Acknowledgements.

The authors wish to thank Vesna Prˇckovska and Paulo Rodrigues, B iomedical image analysis group TU/e, Eindhoven University of Technology, who are gratefully acknowledged for both providing the medical data sets and for their previous efforts, cf.[59, 58], on fast kernel implementations of linear hypoelliptic diffusion on HARDI and DTI (Figure 2 and Figure 3). Furthermore, the authors wish to thank Mark Bruurmijn, master student Biomedical Engineering at TU/e for his DW-MRI visualization programme ListHardiPlot, which enabled us to do all experiments in Mathematica. Finally, the authors wish to thank Ronald Rook from the Department of Mathematics and Computer Science (CASA) TU/e for his suggestions on the finite difference schemes for adaptive diffusions.

A Metric and Lagrangians on $(\mathbb{R}^3 \times S^2, dA^1, dA^2)$

Recall from Figure 6 that our left-invariant diffusions on $\mathbb{R}^3 \times S^2$ take place on the contact/sub-Riemannian manifold $(SE(3), dA^1, dA^2, dA^6)$. On this contact manifold $(SE(3), dA^1, dA^2, dA^6)$ we set the Lagrangian

$$\mathcal{L}_\eta(\dot{\gamma}(s), \ddot{\gamma}(s)) = \frac{2\eta - 1}{2\eta} \left( \frac{\dot{\gamma}_3^2(s)}{D^{13}} + \frac{|\dot{\gamma}_4^2(s)|^2 + |\dot{\gamma}_5^2(s)|^2}{D^{44}} \right) \tag{114}$$

where $\eta > \frac{1}{2}$ and where $D^{13}, D^{44} > 0$ and where $\ddot{\gamma}(s) = (dA^1|_{\dot{\gamma}(s)}, \ddot{\gamma}(s))$ are the components w.r.t. the moving frame of reference attached to the curve, cf. Figure 6. For $\eta \to \infty$ we have a homogeneous Lagrangian and a left-invariant semi-metric on $(SE(3), dA^1, dA^2, dA^6)$ is set by

$$d_{\text{hor}}((y, n), (y', n')) = d((y, R_n), (y', R_{n'}))$$

on $\mathbb{R}^3 \times S^2$. Along horizontal curves $s \mapsto \dot{\gamma}(s) = (x(s), R(s))$ in $SE(3)$ we have $n(s) = R(s)e_z = \dot{x}(s)$ and

$$\|\kappa(s)\|^2 = |(dA^1|_{\dot{\gamma}(s)}, \dot{\gamma}(s))|^2 + |(dA^2|_{\dot{\gamma}(s)}, \ddot{\gamma}(s))|^2,$$

and thereby the metric reduces to

$$d_{\text{hor}}((y, n), (y', n')) = \int_0^L \sqrt{\frac{1}{D^{13}} ||\kappa(s)||^2 + \frac{1}{D^{44}}} \, ds \tag{116}$$

where $s, L > 0$, and $\kappa(s)$ are respectively spatial arclength, total length, and curvatures of the spatial part of the curve. Note that the distance (116) is indeed invariant under the choice of $R_n$ such that Eq. (9) holds, due to left-invariance of (115) and rotation covariance of (116) and $(R_n R_{e_2} e_3)^T = R_{e_2} R_{e_3} R_n$. Furthermore, we note that torsion is implicitly penalized by simultaneous penalization of length and curvature.
After introducing a positive semi-definite\footnote{It need not be strictly positive definite, but the Hörmander condition \cite{47} should not be violated.} left-invariant metric tensor $G : \mathbb{R}^3 \times S^2 \times T(\mathbb{R}^3 \times S^2) \times T(\mathbb{R}^3 \times S^2) \to \mathbb{R}$ given by Eq. (36), we considered the solutions (51) and (53) of the Hamilton-Jacobi equations on $\mathbb{R}^3 \times S^2$:

$$\begin{cases}
\frac{\partial W}{\partial t}(y, n, t) = \pm (H(dW(\cdot, \cdot, t)))(y, n) := \frac{1}{2}(G(y, n))^{-1} \left( dW(\cdot, \cdot, t)|_{y, n}, dW(\cdot, \cdot, t)|_{y, n} \right) \\
W(y, n, 0) = U(y, n)
\end{cases}$$

(117)

where $H$ stands for the Hamiltonian. It is well-known \cite{19} that Hamilton-Jacobi equations in general do not have a unique solution, unless extra requirements such as the practically reasonable viscosity requirement are added.\footnote{Consider for example the initial value problem $\frac{\partial U}{\partial t}(x, t) = (\frac{\partial^2 U}{\partial x^2}(x, t))^2$ and $U(x, 0) = 0$, $x \in \mathbb{R}$, $t \geq 0$, with continuous (non-sensible) solution $U(x, t) = |x| - t$ if $t > |x|$ and zero else. This “nonsense” solution is not a viscosity solution, namely consider $\phi(x, t) = e^{-t} e^{-x^2}$ and $k = -1$ in the Definition of viscosity solutions according to Crandall \cite{19}.}

Our claim was that the solutions (51) and (53) are the unique \cite{19} viscosity solutions of the Hamilton-Jacobi equations (135) and (52).

**Definition 8** Suppose that the Hamiltonian is convex and $H(p) \to \infty$ as $p \to \infty$. Then a viscosity solution is a bounded and continuous (not necessarily differentiable) weak solution $W : (\mathbb{R}^3 \times S^2) \times \mathbb{R}^+ \to \mathbb{R}$ of (117) such that

1. for any smooth function $V : (\mathbb{R}^3 \times S^2) \times \mathbb{R}^+ \to \mathbb{R}$ such that $W - V$ attains a local maximum at $(y_0, n_0, t_0)$ one has

$$\frac{\partial V}{\partial t}(y_0, n_0, t_0) \mp (H(dV(\cdot, \cdot, t)))(y_0, n_0) \leq 0.$$ (118)

2. for any smooth function $V : (\mathbb{R}^3 \times S^2) \times \mathbb{R}^+ \to \mathbb{R}$ such that $W - V$ attains a local minimum at $(y_0, n_0, t_0)$ one has

$$\frac{\partial V}{\partial t}(y_0, n_0, t_0) \mp (H(dV(\cdot, \cdot, t)))(y_0, n_0) \geq 0.$$ (119)

We will first provide a quick review of Hamilton-Jacobi theory, the Hopf-Lax formula and erosions on respectively $\mathbb{R}^4$ and on the Heisenberg group $(SE(3))_0$ that we obtain by contraction from $SE(3)$ and which serves as a local approximation of $SE(3)$, as explained in Section 10.1.

**Definition 9** Let $X$ be a normed space, then the Legendre-Fenchel transform $L \mapsto \mathfrak{F}L$ on $X$ is given by

$$(\mathfrak{F}_L)(x) = \sup_{y \in X} \{ \langle x, y \rangle - L(y) \}$$

where $L : X \to \mathbb{R} \cup \infty$ and $\langle x, y \rangle = x(y)$ and $x \in X^*$. In particular if $X = \mathbb{R}^n$ one gets

$$(\mathfrak{F}_L)(x) = \sup_{y \in \mathbb{R}^n} \{ x \cdot y - L(y) \}$$

and in the Lie-algebra $\mathcal{L}(SE(3))$ of left-invariant vector fields on $SE(3)$ we get

$$(\mathfrak{F}_{\mathcal{L}(SE(3))})(L) = \sum_{i=1}^{6} p_i dA_i = \sup_{\sum_{i=1}^{6} c^i A_i} \{ \sum_{i=1}^{6} p_i dA_i, \sum_{j=1}^{6} c^j A_j \} - L(\sum_{i=1}^{6} c^i A_i) = ((\mathfrak{F}_L)(p_1, \ldots, p_6),$$

with $l(c^1, \ldots, c^6) = L(\sum_{i=1}^{6} c^i A_i)$.
Lemma 1 Let $\eta > \frac{1}{2}$. The Legendre-Fenchel transform of the function

$$\mathbb{R}^4 \ni (c^1, c^2, c^4, c^5) \mapsto \frac{2\eta - 1}{2\eta} \left( \frac{(c^1)^2 + (c^2)^2}{D^{11}} + \frac{(c^4)^2 + (c^5)^2}{D^{44}} \right) \in \mathbb{R}$$

is given by

$$\mathbb{R}^4 \ni (p_1, p_2, p_4, p_5) \mapsto \frac{1}{2\eta} \left( D^{11}((p_1)^2 + (p^2)^2) + D^{44}((p_4)^2 + (p_5)^2) \right) \eta \in \mathbb{R}$$

Proof It is well-known that the Fenchel transform of $c \mapsto \frac{1}{a} \| c \|_a^a$ equals $p \mapsto \frac{1}{b} \| p \|_b^b$ with $\frac{1}{a} + \frac{1}{b} = 1$, furthermore $\mathcal{F} \circ D_\lambda = D_{\lambda^{-1}} \circ \mathcal{F}$ where $D_\lambda$ denotes the scaling operator given by $D_\lambda f(x) = f(\lambda^{-1}x)$ from which the result follows by setting $b = 2\eta$, $a = \frac{2\eta}{2\eta - 1}$ and respectively $\lambda = \sqrt{D^{11}}, \sqrt{D^{44}}$.

Corollary 1 Let $\eta > \frac{1}{2}$, $t > 0$, then on $\mathbb{R}^4$ the Hopf-Lax formula is given by

$$w(x, t) := \inf_{y \in \mathbb{R}^4} \inf_{\gamma(0) = y} \left\{ \int_0^t \mathcal{L}_\eta(\dot{\gamma}(s)) \, ds + u(y) \right\} = \min_{y \in \mathbb{R}^4} \{ t \mathcal{L}_\eta \left( \frac{1}{t} (x - y) \right) + u(y) \}, \quad (120)$$

with $w(\cdot, 0) = u$ a given Lipschitz continuous function on $\mathbb{R}^4$, with

$$\mathcal{L}_\eta(\dot{\gamma}(s)) = \mathcal{L}_\eta(\dot{\gamma}_1(s), \dot{\gamma}_2(s), \dot{\gamma}_4(s), \dot{\gamma}_5(s))$$

$$:= \frac{2\eta - 1}{2\eta} \left( \frac{1}{D^{11}} ((\dot{\gamma}_1(s))^2 + (\dot{\gamma}_2(s))^2) + \frac{1}{D^{44}} ((\dot{\gamma}_4(s))^2 + (\dot{\gamma}_5(s))^2) \right) \frac{\eta}{\eta - 1}, \quad (121)$$

and $w(x, t)$ given by (120) is the unique viscosity solution of the Hamilton-Jacobi-Bellman system

$$\begin{cases} \frac{\partial w}{\partial t}(x, t) = -\frac{1}{2\eta} \left( D^{11} \left( \frac{\partial w}{\partial x^1}(x, t) \right)^2 + \frac{\partial w}{\partial x^2}(x, t) \right)^2 + D^{44} \left( \frac{\partial w}{\partial x^4}(x, t) \right)^2 + \frac{\partial w}{\partial x^5}(x, t) \right)^2 \right) \eta, \\
w(x, 0) = u(x) \end{cases}$$

with $x = (x^1, x^2, x^4, x^5) \in \mathbb{R}^4, t \geq 0$. The morphological Green's function of this PDE is given by

$$k_{D^{11}, D^{44}, \eta}^t(x) = t \mathcal{L}_\eta(t^{-1}x) = \frac{2\eta - 1}{2\eta} \left( \frac{1}{D^{11}} ((x^1 - y)^2 + (x^2 - y^2)^2) + \frac{1}{D^{44}} ((x^4 - y)^2 + (x^5 - y^5)^2) \right) \frac{\eta}{\eta - 1}. \quad (122)$$

In the limiting case $\eta \to \infty$ the Lagrangian is homogeneous \(^{10}\) and

$$w(x, t) = \min_y \{ u(y) + \left( \frac{1}{D^{11}} \left( (x^1 - y)^2 + (x^2 - y^2)^2 \right) + \frac{1}{D^{44}} \left( (x^4 - y)^2 + (x^5 - y^5)^2 \right) \right) \} \left( (x^1 - y)^2 + (x^2 - y^2)^2 \right) \} \frac{1}{t} \quad (123)$$

and we arrive at the time-independent Hamilton-Jacobi equation

$$1 = D^{11} \left( \frac{\partial w}{\partial x^1}(x, t) \right)^2 + \frac{\partial w}{\partial x^2}(x, t) \right)^2 + D^{44} \left( \frac{\partial w}{\partial x^4}(x, t) \right)^2 + \frac{\partial w}{\partial x^5}(x, t) \right)^2, \quad (124)$$

In the limiting case $\eta \downarrow \frac{1}{2}$ the Hamiltonian is homogeneous and the Hopf-Lax formula reads

$$w(x, t) = \min_{y \in \mathbb{R}^4} \{ k_{D^{11}, D^{44}, \eta}^t(x - y) + u(y) \}$$

where the flat morphological erosion kernel is given by

$$k_{D^{11}, D^{44}, \eta}^t(x) = \begin{cases} 0 & \text{if } \frac{(y^1)^2 + (y^2)^2}{D^{11}} + \frac{(y^4)^2 + (y^5)^2}{D^{44}} \leq t^2, \\
\infty & \text{else} \end{cases}. \quad (125)$$

\(^{10}\) The corresponding Hamiltonian $H(\tilde{p}) = \mathcal{L}(\dot{\gamma})$ is homogeneous as well, but now with respect to $\tilde{p}_i := \frac{1}{\eta} \frac{\partial \mathcal{L}(\dot{\gamma})}{\partial \dot{\gamma}_i}$, [ch.3][66].
**Proof** Directly follows by Lemma 1 and [34, ch:3(Thm 4), ch:10 (Thm 1, Thm 3)]. For the special case of a homogeneous Lagrangian \((\eta \to \infty)\), see [66, Ch:3].

**Remark 5** We parameterized elements in \(\mathbb{R}^4\) by means of \(y = (y^1, y^2, y^3, y^5)\) since we want to stress the analogy to Hamilton-Jacobi equations on \(\mathbb{R}^3 \times S^2\).

**Lemma 2** (semigroup property of erosion operator on \(\mathbb{R}^3 \times S^2\))

Let \(\eta > \frac{1}{2}\) and let \(D^{11}, D^{44}\). Let the morphological Green’s function be defined as

\[
k_t^{D^{11}, D^{44}, \eta}(y, n) := \inf_{\gamma = (x(\cdot), y(\cdot)) \in C^\infty((0, t), SE(3)), \gamma(0) = (0, t = Re_z), \gamma(t) = (y, R_A), (dA^1 |_{\gamma(t)}, \gamma) = 0} \int_0^t \mathcal{Z}_\eta(\gamma(p), \dot{\gamma}(p)) \, dp, \tag{122}
\]

with

\[
\mathcal{Z}_\eta(\gamma(p), \dot{\gamma}(p)) := \mathcal{L}_\eta((dA^1 |_{\gamma(p)}, \dot{\gamma}(p)), \ldots, (dA^3 |_{\gamma(p)}, \dot{\gamma}(p)))
\]

where we recall Eq. (121) and with \(\mathbb{R}^3 \times S^2\)-“erosion arclength” given by

\[
p(\tau) = \int_0^\tau \sqrt{G_{\gamma(\tau)}(\dot{\gamma}(\tau), \dot{\gamma}(\tau))} \, d\tau = \int_0^\tau \sqrt{\sum_{i \in \{1, 2, 4, 5\}} \frac{1}{|d\gamma|} (dA^i |_{\gamma(\tau)}, \dot{\gamma}(\tau))^2} \, d\tau
\]

with \(D^{11} = D^{22}\) and \(D^{44} = D^{55}\) and with left-invariant metric tensor \(G(\cdot, \cdot) = \lim_{\eta \to \infty} (\mathcal{Z}_\eta(\cdot, \cdot))^2\). Then we have the following identity

\[
k_{t-\tau}^{D^{11}, D^{44}, +} (k_t^{D^{11}, D^{44}, \eta, +} \ominus U) = k_t^{D^{11}, D^{44}, \eta, +} \ominus U, \tag{124}
\]

for all \(\tau \in [0, t]\) and all Lipschitz continuous functions \(U : \mathbb{R}^3 \times S^2 \to \mathbb{R}\), where we recall that our erosion operator \(\ominus\) is defined in Eq. (39).

**Proof** First of all we note that \(D^{11} = D^{22}\) and \(D^{44} = D^{55}\) are necessary requirements for a well-defined \(k_t^{D^{11}, D^{44}, \eta, +} : \mathbb{R}^3 \times S^2 \to \mathbb{R}^+\) and in particular (as \(\eta \to \infty\)) a well-defined metric on the quotient \(\mathbb{R}^3 \times S^2 = (\mathbb{R}^3 \times SO(3))/\{(0) \times SO(2)\}\). Here the limit \(\lim_{\eta \to \infty} \mathcal{Z}_\eta(\cdot, \cdot)\) is homogeneous in the second entry so that

\[
\mathcal{Z}_\infty(\gamma(p), \frac{d\gamma}{dp}) = \mathcal{Z}_\infty \left(\gamma(p(\tau)), (\mathcal{Z}_\infty(\gamma(p(\tau)), \frac{d\gamma}{d\tau}))^{-1} \frac{d\gamma}{d\tau}\right) = 1 \quad \text{and} \quad \lim_{\eta \to \infty} k_t^{D^{11}, D^{44}, \eta, +}(y, n) = t,
\]

so \(t > 0\) is the total length of the curve in the sub-Riemannian manifold \((\mathbb{R}^3 \times S^2, dA^3)\) and where \(\rho\) is the arc-length parameter in \((\mathbb{R}^3 \times S^2, dA^3)\) since connecting curves over which is optimized are not allowed to use the \(A_3\)-direction in the tangent bundle (practical motivation: we want to erode orthogonal to the fibers).

Secondly, we recall that functions \(U : \mathbb{R}^3 \times S^2 \to \mathbb{R}\) are related to functions \(\tilde{U} : SE(3) \to \mathbb{R}\) with invariance property \((\forall g \in SE(3) \forall \nu = (0, R_{e_z}, n) \in SE(3) \forall \nu \in \mathbb{R}^3) \tilde{U}(gh) = \tilde{U}(g)\) by means of

\[
\tilde{U}(g) = \tilde{U}(x, R) = U(x, Re_z),
\]

with \(g = (x, R) \in SE(3), y \in \mathbb{R}^3, e_z = (0, 0, 1)^T\). We apply this identification by setting

\[
\tilde{W}(g, t) := \inf_{q \in SE(3)} \left\{ k_{t-\tau}(q^{-1} g) + \tilde{U}(g) \right\}
\]

for all \(g \in SE(3)\) and \(t \geq 0\). Consequently, we may rewrite our Eq. (124) as

\[
\tilde{W}(g, t) = \inf_{v \in SE(3)} \left\{ k_{t-\tau}(v^{-1} g) + \tilde{W}(v, \tau) \right\}, \tag{125}
\]

52
where we use short notation \( \tilde{k}_t(y, R) := k_t^{D^{11}, D^{44}, n+, \cdot}(y, R e) \).

Thirdly, we apply basically the same approach as in [52, Thm.1] where we replace the Heisenberg group by the 3D-Euclidean motion group \( SE(3) \) where in this lemma we carefully omit scaling properties of the Lagrangian that do hold for the Heisenberg group, but not on the \( SE(3) \) (even though one has the contraction \( \lim_{q \to 0}(SE(3))_q = (SE(3))_0 \) which serves as a local nilpotent approximation, [67]). We shall return to these local approximations later when we derive approximations of \( k_t^{D^{11}, D^{44}, n+, \cdot}(y, n) \). For, now let us proceed with proving Eq. (125).

In general one has

\[
\tilde{k}_t(v^{-1}g) \leq \tilde{k}_t(v^{-1}q) + \tilde{k}_{t-\tau}(q^{-1}g)
\]

(126)

for all \( g, h, v \in SE(3) \) and all \( \tau \in [0, t] \) as the concatenation of two optimal curves yields an admissible curve over which is optimized in the left hand side. Here equality is obtained if \( v^{-1}q \) is on the minimizing curve between \( e \) and \( v^{-1}g \), i.e. by left-invariance \( g \) is on the minimizing curve between \( e \) and \( v^{-1}q \). Now due to continuity and convexity of \( (c^1, c^2, c^3, c^5) \mapsto \mathcal{L}_\eta(c^1, c^2, c^4, c^5) \) the infimum in (125) and (122) is actually a minimum and therefore we can choose \( v \in SE(3) \) such that

\[
\tilde{W}(g, \tau) = \tilde{k}_t(v^{-1}q) + \tilde{U}(v).
\]

Then by Eq. (126) one has

\[
\tilde{W}(g, t) \leq \tilde{k}_t(v^{-1}g) + \tilde{U}(v) \leq \tilde{k}_t(v^{-1}q) + \tilde{k}_{t-\tau}(q^{-1}g) + \tilde{U}(v) = W(g, \tau) + \tilde{k}_{t-\tau}(q^{-1}g)
\]

for all \( q \in SE(3) \) and thereby (by taking the infimum over all \( q \)) we obtain

\[
k_t^{D^{11}, D^{44}, n+, \cdot}(k_{t-\tau}^{D^{11}, D^{44}, n+, \cdot} \circ U) \geq k_t^{D^{11}, D^{44}, n+, \cdot} \circ U.
\]

(127)

So in order to prove (124) it remains to be shown that \( k_t^{D^{11}, D^{44}, n+, \cdot}(k_{t-\tau}^{D^{11}, D^{44}, n+, \cdot} \circ U) \leq k_t^{D^{11}, D^{44}, n+, \cdot} \circ U \). Let \( w \in SE(3) \) such that

\[
\tilde{W}(g, t) = \min_{v \in SE(3)} \tilde{k}_t(v^{-1}g) + \tilde{U}(v) = \tilde{k}_t(w^{-1}g) + \tilde{U}(w),
\]

now take \( g \) as a point along the minimizing curve between \( g \) and \( w \) where the vertical \( \mathbb{R}^3 \times S^2 \) arc-length equals \( p = \tau \). Then we have

\[
\tilde{W}(g, t) = \tilde{k}_t(w^{-1}g) + \tilde{k}_{t-\tau}(q^{-1}g) + \tilde{U}(w) \geq \tilde{k}_{t-\tau}(q^{-1}g) + \tilde{W}(q, \tau) \geq \min_{\tau \in SE(3)} \{ \tilde{k}_{t-\tau}(r^{-1}g) + \tilde{W}(r, \tau) \}
\]

from which the result follows.

\[ \square \]

**Lemma 3** Let \( k_t^{D^{11}, D^{33}, n, \pm} \) respectively denote the viscosity solution of Eq. (135), Eq. (52), with initial condition \( \pm \delta_C, \eta > \frac{1}{2}, D^{11}, D^{33} > 0 \). Horizontal diffusions on \( \mathbb{R}^3 \times S^2 \) require the filtration (76) of the Lie-algebra. Vertical diffusions, erosions and dilations on \( \mathbb{R}^3 \times S^2 \) require the filtration

\[
g_0 := \{ A_1, A_2, A_4, A_5 \} \subset g_1 := \{ A_1, A_2, A_3, A_4, A_5, A_6 \}
\]

(128)

and thereby we have the following estimate for \( h > 0 \) sufficiently small

\[
\frac{2\eta - 1}{2\eta} C^{\frac{2\eta - 1}{\eta - 1}} \sum_{i \in \{1, 2, 4, 5\}} c^i A_i^{\frac{2\eta - 1}{\eta - 1}} \leq k_h^{D^{11}, D^{44}, n, \cdot} \left( \left[ \exp \left( \frac{h}{h} \sum_{i \in \{1, 2, 4, 5\} \ c^i A_i} \right) \right] \right) \leq \frac{2\eta - 1}{2\eta} C^{\frac{2\eta - 1}{\eta - 1}} \sum_{i \in \{1, 2, 4, 5\}} c^i A_i^{\frac{2\eta - 1}{\eta - 1}}
\]

(129)
with \( A_i = A_i|_e \in T_e(\text{SE}(3)) \), \( c^i \in \mathbb{R} \), \( C \geq 1 \) and \( \left| \sum_{i \in \{1,2,4,5\}} c^i A_i \right| = \sqrt{\sum_{i \in \{1,2,4,5\}} |c^i|^2} \) with \( D^{11} = D^{22} \) and \( D^{44} = D^{55} \) and where \( \left( \exp \left( h \sum_{i \in \{1,2,4,5\}} c^i A_i \right) \right) \) denotes the left coset in \( \mathbb{R}^3 \times S^2 = \text{SE}(3)/(\{0\} \times SO(2)) \) associated to the group element \( \exp \left( h \sum_{i \in \{1,2,4,5\}} c^i A_i \right) \in SE(3) \).

**Proof** First of all we set \( D^{44} = D^{11} = 1 \) as the other cases follow by scaling. The theory of weighted subcoercive operators on Lie groups applies, [67, ch.1.6] where one should consider the special case \( \mathcal{U} = \mathcal{R}, G = \text{SE}(3) \) and algebraic basis \( \zeta_0 \) given by (128) as erosion/dilation only takes place in the directions \( A_1, A_2, A_4 \) and \( A_5 \) (i.e. \( G \)-orthogonal to \( A_3 \)). As a result we must assign the following weights to the Lie-algebra elements \( w_1 = w_2 = w_3 = w_4 = 1 \) and \( w_5 = w_6 = 2 \). The solution of the Hamilton-Jacobi equation (35) describes the propagation of “balls” in \( \mathbb{R}^3 \times S^2 = \text{SE}(3)/(\{0\} \times SO(2)) \) centered around unity element \( e = (0, e_2) \equiv \{ (0, R_{e_i, \alpha}) \mid \alpha \in [0, 2\pi) \} \in \mathbb{R}^3 \times S^2 \), as we show in Appendix I. Its Green’s function is given by (122) as we will show later in Theorem 4. with morphological Green’s function given by Eq. (122) By means of (122) we obtain the estimate

\[
\sum_{i \in \{1,2,4,5\}} c^i A_i \leq \left( d_{SE(3)}((y, R_n), (0, I)) \right)^{\frac{2\eta}{\eta}} \leq \frac{2\eta - 1}{2\eta} h^{-\frac{1}{\eta}} \left( d_{SE(3)}((y, R_n), (0, I)) \right)^{\frac{2\eta}{\eta}},
\]

where \( d_{SE(3)} : SE(3) \times SE(3) \to \mathbb{R}^+ \) is the metric defined by

\[
d_{SE(3)}(g, v) = d(v^{-1}g, e) = d(g, e) = \inf \left\{ \delta > 0 \mid \exists \gamma \in C^1([0,1], SE(3)) : \gamma(0) = e \text{ and } \gamma(1) = g \right\},
\]

and for all \( g = v^{-1}g, v, g \in SE(3) \), where \( \gamma^i(s) := \langle dA^i, \gamma(s) \rangle, i = 1, \ldots, 6 \), with \( s = pt^{-1} \). Now by the general results in [67, Prop. 6.1] (where one must set Hilbert space \( H = L^2(\mathbb{S}^2) \), group \( G = \text{SE}(3) \), right-regular representation \( \mathcal{U} = \mathcal{R} \) and filtration (128)) we deduce that there exists \( C \geq 1 \) and \( \epsilon > 0 \) such that for all \( 0 < t = h < \epsilon \) one has

\[
C^{-1} \left| \sum_{i \in \{1,2,4,5\}} c^i A_i \right| \leq d_{SE(3)}(e, \sum_{i \in \{1,2,4,5\}} c^i A_i, e) \leq C \left| \sum_{i \in \{1,2,4,5\}} c^i A_i \right| = C \left( \sum_{i \in \{1,2,4,5\}} |c^i|^2 \right)^{\frac{1}{2}}.
\]

Now the result (129) follows by (130) and (131) where we note that \( h^{\frac{1}{\eta}} h^{-\frac{1}{\eta}} = 1 \). \( \square \)

Clearly, not every element \( (y, R_{e_i, \alpha}) \in SE(3) \) is reached by an exponential curve of the type \( h \mapsto e^{h \sum_{i \in \{1,2,4,5\}} c^i A_i} \). In fact, by the Campbell-Baker-Hausdorff formula and the commutator table (29) one has

\[
(h(y^1, y^2, 0), R_{e_i, \gamma h R_{e_i, \beta h}}) = (h(y^1, y^2, 0), I)(0, R_{e_i, \gamma h R_{e_i, \beta h}}) = \exp\{h(y^1 A_1 + y^2 A_2)\} \exp\{h \beta A_3\} = \exp\{h(y^1 A_1 + y^2 A_2)\} \exp\{h \gamma A_4 + \beta h A_5\} = \exp\{h(y^1 A_1 + y^2 A_2)\} \exp\{h \gamma A_4 + \beta h A_5 + \frac{1}{2} \beta h^2 A_4, A_5\} = \exp\{h(y^1 A_1 + y^2 A_2) + h \gamma A_4 + h \beta A_5 + \frac{1}{2} \beta h^2 (y^3 \beta - y^3 \gamma) A_3 + \frac{1}{2} h^2 (y^3 \gamma) A_6 + O(h^3)\}
\]

and consequently, one has

\[
(130)
\]

**Lemma 4** Let \( \Omega_e \) be a compact set around the unity element \( e = (0, e_2) \equiv \{ (0, I) \} = \{ (0, R_{e_i, \alpha}) \mid \alpha \in [0, 2\pi) \} \) within \( \mathbb{R}^3 \times S^2 \), then there exists an \( \epsilon > 0 \) and \( C > 1 \) such that for all \( h < \epsilon \) one has the following uniform estimate

\[
(131)
\]

\[\text{In fact this estimate holds uniformly for the groups } (SE(3))_{\mathcal{U}}, \mathcal{U} \in [0, 1], \text{ of Section 10.1 which share the same Lie-algebra.}\]
on compact sets

\[ \frac{2n-1}{2\eta} h \pi^{n/2} C^{\frac{2n}{\pi^n}} \left( \sum_{i=1}^n (c_i^2)^{\frac{2}{n}} \right)^{\frac{n}{n-1}} \leq k_h((y, n(\beta, \gamma))) = \frac{k_h(\exp\{\sum_{i=1}^n c_i A_i h^w_i\})}{h} \]

\[ \leq h^{-\frac{2n-1}{2\eta}} C^{\frac{2n}{\pi^n}} \left( \sum_{i=1}^n (c_i^2)^{\frac{2}{n}} \right)^{\frac{n}{n-1}} \]

for all \((y, n(\beta, \gamma) \equiv [\exp\{\sum_{i=1}^n c_i A_i h^w_i\}] \in \Omega_e,\) with \(w_1 = w_2 = w_5 = w_4 = 1\) and \(w_3 = w_6 = 2\) and \(c_i := c_i(y, \alpha = 0, \beta, \gamma) = c_i(y, \tilde{\alpha} = 0, \tilde{\beta}, \tilde{\gamma}),\) given by Eq. (75) and (72).

**Proof** Regarding the assignment of the weights to the Lie-algebra elements we refer to Eq. (132) and (128). Regarding the logarithmic mapping in \(SE(3)\) we recall Section 9.1. Akin to the metric (161), the formula (122) is well-defined on the partition \(\mathbb{R}^3 \times S^2 := SE(3)/(\{0\} \times SO(2))\) of left cosets. However as we have the restriction \(\langle dA^0, \dot{\gamma} \rangle = \langle d\tilde{\alpha}, \dot{\gamma} \rangle = \langle d\tilde{\alpha}, \dot{\gamma} \rangle = 0\) we must apply a consistent cross-section in \(\mathbb{R}^3 \times S^2.\) For convenience, we take the unique element from the left cosets with \(\tilde{\alpha} = 0\) in the Euler-angle parametrization in both the initial point \((0, R_{e_0} = I)\) and endpoint \((y, R_\alpha = R_{e_\alpha} R_{e_0} \beta)\) of the curve. For the rest the proof is the same as the proof of Lemma 3. \(\square\)

**Corollary 2** Let \(\eta > \frac{1}{2}, D^{11} > 0, D^{44} > 0, w_1 = w_2 = w_4 = w_5 = 1, w_3 = w_6 = 2.\) For the morphological erosion (+) and dilation kernel (-) on \(\mathbb{R}^3 \times S^2\) one can use the following asymptotical formula

\[ k_{D^{11}, D^{44}, \eta, \pm}(y, \mathbf{n}(\tilde{\beta}, \tilde{\gamma})) = \pm \frac{2\eta - 1}{2\eta} C^{\frac{2n}{\pi^n}} t^{-\frac{1}{2n}} \left( \sum_{i=1}^n \frac{|c_i(y, \tilde{\alpha} = 0, \tilde{\beta}, \tilde{\gamma})|^2}{D^{11}_{w_i}} \right)^{\frac{n}{n-1}} \]  

for sufficiently small time \(t > 0.\)

**Remark 6** Now according to Theorem 3, the covariantly constant curves with respect to the Cartan connection are the exponential curves. Now suppose \((y, R_\alpha)\) with \(R_\alpha e_\alpha = n\) and suppose that \(R_\alpha\) has \(\alpha = 0\) in its Euler angle parametrization (12). If \((y, n) = \left[ e^{c \in \{1, 2, 4, 5\} c_i A_i} \right]\) then

\[ [0, 1] \ni s \mapsto \tilde{\gamma}(s) := e^{s \sum_{i=1}^5 c_i A_i} \]

is the unique covariantly constant (i.e. auto-parallel) curve connecting \((0, I)\) with \((y, R_\alpha)\) in \(SE(3).\) Now, according to Theorem 3 the Cartan connection has non-vanishing torsion and thereby covariantly constant curves need not coincide with curves (that we call geodesics) that minimize

\[ \inf_{\gamma = \langle \gamma(t) \rangle, \gamma(0) = 0, \gamma(t) = y, \gamma_0 = 0, \gamma(t) \in C^\infty((0, t), SE(3)), (dA^0)_{\gamma_\gamma} = 0} \int_0^t \mathcal{L}_\eta(\dot{\gamma}(p), \dot{\gamma}(p)) \, dp. \]  

If we now substitute \(\tilde{\gamma}(s)\) into (134) then one has \(\tilde{\gamma}_i(s) = \langle dA^i|_{\tilde{\gamma}(s)}, \tilde{\gamma}(s) \rangle = c_i, i \in \{1, 2, 4, 5\}\) and consequently we obtain (we again set \(s = t^{-\frac{1}{2}}\) as in the proof of Lemma 3)

\[ t \int_0^1 \mathcal{L}_\eta(\tilde{\gamma}(s), t^{-\frac{1}{2}} \frac{d}{ds} \tilde{\gamma}(s)) \, ds = \frac{2\eta - 1}{2\eta} \left( \sum_{\{1, 2, 4, 5\}} \frac{|c_i|^2}{D^{11}_{w_i}} \right)^{\frac{n}{n-1}} t^{-\frac{1}{2n}}, \]

which is precisely the weighted modulus on the Lie-algebra! So from Lemma 3 we observe that the discrepancy between covariantly constant curves (exponential curves) and energy minimizers (geodesics) that is due to the torsion of the Cartan connection (so that the standard result on the geodesic equation [49, p.172-174] does not apply) has a minor effect for small time steps (that is if \((y, n)\) can be connected via a suitable covariantly constant curve).
Lemma 5 Let $c^i \in \mathbb{R}$, $i = 1, 2, 4, 5$ and $\eta > \frac{1}{2}$ then

$$
\lim_{h \to 0} \frac{h^{D^{11},D^{44},\eta,+}}{h} \left[ \exp \left( \frac{h}{\eta} \sum_{i \in \{1,2,4,5\}} c^i A_i \right) \right] = 2^{\eta - 1} \frac{\eta}{2\eta} \left| \sum_{i \in \{1,2,4,5\}} \frac{c^i}{\sqrt{D^{ii}}} A_i \right|^{\frac{2\eta}{\eta}} = 2^{\eta - 1} \frac{\eta}{2\eta} \left| \sum_{i \in \{1,2,4,5\}} \frac{|c|^2}{D^{ii}} \right|^{\frac{2\eta}{\eta}}.
$$

Proof Consider Eq. (122), then to each $C^2$-curve with $\langle dA^3|_{\gamma}, \gamma \rangle = \langle dA^0|_{\gamma}, \gamma \rangle = 0$, we have the following $C^1$-functions

$$[0,h] \ni p \mapsto \gamma(p) := \langle dA^i|_{\gamma(p)}, \gamma(p) \rangle \in \mathbb{R}$$

for $i \in \{1,2,4,5\}$. By applying a first order Taylor-approximation around $p = 0$ we obtain

$$\lim_{h \to 0} h^{-1} \int_0^h L_{\eta} \left( \frac{1}{\sqrt{D^{11}}} \gamma^1(p), \frac{1}{\sqrt{D^{44}}} \gamma^2(p), \frac{1}{\sqrt{D^{ii}}} \gamma^4(p), \frac{1}{\sqrt{D^{ii}}} \gamma^5(p) \right) dp
= \lim_{h \to 0} h^{-1} \int_0^h L_{\eta} \left( \frac{1}{\sqrt{D^{11}}} \gamma^1(0) + O(p), \frac{1}{\sqrt{D^{44}}} \gamma^2(p) + O(p), \frac{1}{\sqrt{D^{ii}}} \gamma^4(0) + O(p), \frac{1}{\sqrt{D^{ii}}} \gamma^5(0) + O(p) \right) dp
= O(h^{\frac{2\eta}{\eta}} h^{-1}) + 2^{\eta - 1} \frac{\eta}{2\eta} \left( \sum_{i \in \{1,2,4,5\}} \frac{1}{\sqrt{D^{ii}}} (\gamma^i(0))^2 \right)^{\frac{2\eta}{\eta}}$$

and $O(h^{\frac{2\eta}{\eta}} h^{-1}) = O(h^{\frac{1}{\eta}}) \to 0$ as $h \downarrow 0$ (since $\eta > \frac{1}{2}$) the result follows by the definition of the morphological kernel, Eq. (122).

Theorem 4 The viscosity solutions of

$$\left\{ \begin{array}{l} \frac{\partial W}{\partial t} (y, n, t) \mp \frac{1}{2\eta} \left( G_{(y,n)}^{-1} \left( dW(\cdot, \cdot, t)|_{y,n}, dW(\cdot, \cdot, t)|_{y,n} \right) \right)^\eta = 0 \\
W(y, n, 0) = U(y, n) \end{array} \right. \tag{135}$$

with $G_{(y,n)} = g_{ii} \ dA^i|_{y,n} \otimes dA^i|_{y,n}$ with $g_{ii} = \frac{1}{D^{ii}}$ with $D^{11} = D^{22}, D^{44} = D^{55} > 0$ are respectively given by (+ case) left-invariant erosion

$$(k_t^{D^{11},D^{44},\eta,+} \otimes_{\mathbb{R} \times S^2} U)(y, n) = \inf_{(y', n') \in \mathbb{R} \times S^2} \left[ U(y', n') + k_t^{D^{11},D^{44},\eta,+} (R^T_{n'} (y - y'), R^T_{n'} n) \right]. \tag{136}$$

and (− case) left-invariant dilation

$$(k_t^{D^{11},D^{44},\eta,-} \otimes_{\mathbb{R} \times S^2} U)(y, n) = \sup_{(y', n') \in \mathbb{R} \times S^2} \left[ k_t^{D^{11},D^{44},\eta,-} (R^T_{n'} (y - y'), R^T_{n'} n) + U(y', n') \right]. \tag{137}$$

Proof The proof consists of two parts, first we must show that they are indeed solutions and then we show that they are viscosity solutions. We will only consider the erosion case since the dilation case can be treated analogously.

Part I. This part consists of two subparts. In part Ia we will show that if we set

$$W(y, n, t) := (k_t^{D^{11},D^{44},\eta,+} \otimes_{\mathbb{R} \times S^2} U)(y, n)$$

with morphological kernel given by (122) then

$$\frac{\partial W}{\partial t} (y, n, t) \mp \frac{1}{2\eta} \left( G_{(y,n)}^{-1} \left( dW(\cdot, \cdot, t)|_{y,n}, dW(\cdot, \cdot, t)|_{y,n} \right) \right)^\eta \leq 0. \tag{138}$$

Subsequently, in part Ib we show that

$$\frac{\partial W}{\partial t} (y, n, t) \mp \frac{1}{2\eta} \left( G_{(y,n)}^{-1} \left( dW(\cdot, \cdot, t)|_{y,n}, dW(\cdot, \cdot, t)|_{y,n} \right) \right)^\eta \geq 0. \tag{139}$$

so that part I is finished.
part Ia  Again we resort to evolutions on the full group $SE(3)$ by setting \( \tilde{W}(y, R, t) = W(y, R e_t, t) \) for all \( y \in \mathbb{R}^3, R \in SO(3) \), \( t > 0 \). Then for all \( A = \sum_{i \in \{1,2,4,5\}} c_i A_i \) one has by Lemma 2 that

\[
W(g e^{hA}, t + h) = \min_{v \in SE(3)} \tilde{k}_h^{D^{11},D^{44},n_+}(v^{-1} g e^{hA}) + \tilde{W}(v, t)
\]

for all \( g = (y, R) \) and consequently, one has

\[
\frac{\partial \tilde{W}(g, t)}{\partial t} + c^i A_i |_g \tilde{W}(g, t) \leq \mathcal{L}_\eta(c)
\]

for all \( c = (c^1, c^2, c^4, c^5) \in \mathbb{R}^4 \). So by subtracting the Lagrangian and taking the maximum over all \( c \) we apply the Fenchel transform of the Lagrangian which yields the Hamiltonian, i.e.

\[
\tilde{W}(g, t) = \tilde{W}(g^*, 0) + \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g).
\]

Then we have

\[
\tilde{W}(g, t) - \tilde{W}(g e^{-\frac{b}{h} A + \frac{b}{h} A^*, t-h}) \geq \frac{1}{h} \left( \tilde{W}(g, 0) + \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g) - \tilde{W}(g, 0) + \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g e^{-\frac{b}{h} A} e^{\frac{b}{h} A^*}) \right)
\]

\[
= \frac{1}{h} \left( \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g) - \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g e^{-\frac{b}{h} A} e^{\frac{b}{h} A^*}) \right)
\]

where \( g = e^A = \sum_{i=1}^6 c_i A_i \) and \( g^* = e^{A^*} = \sum_{i=1}^6 (c^*_i)^* A_i \in SE(3) \). If we now let \( h \downarrow 0 \) then we obtain

\[
\lim_{h \downarrow 0} \tilde{W}(g, t) = \tilde{W}(g e^{-\frac{b}{h} A^*}, t) - \tilde{W}(g e^{-\frac{b}{h} A - \frac{b}{h} A^*}, t-h) \geq \lim_{h \downarrow 0} \left( \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g) - \tilde{k}_t^{D^{11},D^{44},n_+}((g^*)^{-1} g e^{-\frac{b}{h} A} e^{\frac{b}{h} A^*}) \right)
\]

where we applied Lemma 2 and where we note that by the Campbell-Baker-Hausdorff formula

\[
e^{-\frac{b}{h} A} e^{\frac{b}{h} A^*} = e^{-\frac{b}{h} (A-A^*)} + \frac{b^2}{2h^2} [A,A^*] + O(h^3)
\]

so that

\[
\tilde{W}(g e^{-\frac{b}{h} (A-A^*)}, t-h) = \tilde{W}(g e^{-\frac{b}{h} A} e^{\frac{b}{h} A^*}, t-h) + O(h^2)
\]
Similarly one can show that dilation (39) with the kernel $k$ indeed satisfies (118) at a location $(y_0, n_0, t_0)$ in $(\mathbb{R}^3 \times S^2) \times R^+$ where $W - V$ attains a local maximum. The other case (119) can be shown analogously. Similarly one can show that dilation (39) with the kernel $k_{t}^{D^{11}, D^{44}, \eta, -} = -k_{t}^{D^{11}, D^{44}, \eta, +}$ is the viscosity solution of Eq. (52).

First of all it follows by left-invariance (and the fact that $SE(3)$ acts transitively on $\mathbb{R}^3 \times S^2$ by means of Eq. (18)) that without loss of generality we can restrict ourselves to the case $\langle y_0, n_0 \rangle = (\mathbf{0}, e_z)$ and furthermore, by the semigroup property Lemma 2, we can, again without loss of generality, restrict ourselves to the case $t_0 = 0$. Since $W - V$ attains a maximum in $(\mathbf{0}, e_z, 0)$, there exists a small open set $\Omega$ around $(\mathbf{0}, e_z, 0)$ in $(\mathbb{R}^3 \times S^2) \times R$ where

$$W(y, n, t) - V(y, n, t) \leq W(y, n, 0) - V(y, n, 0) \leq 0 \quad (144)$$

Furthermore we have by Eq. (136) that

$$W(y, n, t) \geq W(\mathbf{0}, e_z, 0) + k_{t}^{D^{11}, D^{44}, \eta, +}(y, n), \quad (145)$$

for all $(y, n) \in \mathbb{R}^3 \times S^2$. Combining the estimates (144) with (145) yields

$$-V(\mathbf{0}, e_z, 0) + V(y, n, t) \leq W(y, n, t) - W(\mathbf{0}, e_z, 0) \leq k_{t}^{D^{11}, D^{44}, \eta, +}(y, n) \quad (146)$$

for almost every $g \in \mathbb{R}^3 \times S^2$ (where $\hat{W}(\cdot, t - h)$ is differentiable).

Recall that the left-invariant vector fields are obtained by the derivative of the right-regular representation $A_i = dR(A_i) = A_i |_{\{0, t\}}$ and as a result the limit in the right-hand side of (142) equals

$$\lim_{h \to 0} \frac{\hat{W}(g, t - h) - \hat{W}(g, t)}{h} = \frac{\partial}{\partial t} \hat{W}(g, t) - \sum_{i \in \{1, 2, 4, 5\}} \left( \frac{c^i - (c^*)^i}{t} \right) A_i |_g \hat{W}(g, t).$$

Furthermore, we can assume without loss of generality that $c^3 = c^6 = (c^*)^3 = (c^*)^6 = 0$, i.e.

$$A - A^* \in \text{span}\{A_1, A_2, A_4, A_5\}. \quad (143)$$

To this end we recall both $\mathbb{R}^3 \times S^2 = SE(3)/\{\{0\} \times SO(2))$ and $\hat{W}(g, t) = W(y, R(\mathbf{e}_z), t), g \in SE(3)$ so that $\hat{W}(g, t) = \hat{W}(ge^{\alpha A_0}, t)$ and $\bar{k}_{t}^{D^{11}, D^{44}, \eta, +}(e^{-\beta A_0}ge^{\alpha A_0}) = \bar{k}_{t}^{D^{11}, D^{44}, \eta, +}(g)$ for all $\alpha, \beta \in \mathbb{R}$ and by the Campbell-Baker-Hausdorff formula one can always find $\alpha, \beta \in \mathbb{R}$ such that

$$\log(e^{\alpha A_0}) - \log(e^{\beta A_0}e^{\alpha A_0}) \in \text{span}\{A_1, A_2, A_4, A_5\}.$$

Assumption (143) allows us to compute the limit in the final right-hand side of inequality (142) by means of Lemma 5 and we obtain

$$\frac{\partial}{\partial t} \hat{W}(g, t) + \sum_{i \in \{1, 2, 4, 5\}} (c^i - (c^*)^i) A_i |_g \hat{W}(g, t) \geq \lim_{h \to 0} \bar{k}_{t}^{\alpha A_0}(\frac{h}{h - A - A^*}) = \mathcal{L}_h \left( \frac{c^3 - (c^*)^3}{t}, \frac{c^4 - (c^*)^4}{t}, \frac{c^5 - (c^*)^5}{t} \right).$$

from which we conclude :

$$\frac{\partial}{\partial t} \hat{W}(g, t) + \frac{1}{2\eta} \left( \sum_{i \in \{1, 2, 4, 5\}} (A_i, \hat{W}(g, t))^2 \right)^{2\eta} = \frac{\partial}{\partial t} \hat{W}(g, t) + \sup_{\hat{\alpha} \in \mathbb{R}^k} \left( \sum_{i \in \{1, 2, 4, 5\}} (c^i - (c^*)^i) A_i |_g \hat{W}(g, t) - \mathcal{L}_h(\hat{\alpha}) \right) \geq \frac{\partial}{\partial t} \hat{W}(g, t) + \sum_{i \in \{1, 2, 4, 5\}} (c^i - (c^*)^i) A_i |_g \hat{W}(g, t) - \mathcal{L}_h(\hat{\alpha}) \left( \frac{c^3 - (c^*)^3}{t}, \frac{c^4 - (c^*)^4}{t}, \frac{c^5 - (c^*)^5}{t} \right)$$

from which the result (139) follows.
locally around $(0, e_z, 0)$, that is within $\Omega$. Or equivalently for the corresponding function on $SE(3)$ given by $\tilde{V}(x, R) = V(x, Re_z)$ we have
\[
\frac{d}{dt}(\tilde{V}(0, 0) + \tilde{V}(y, R_n, t)) \leq \frac{2\eta - 1}{2\eta} | \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i| \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i| \approx \frac{2\eta - 1}{2\eta}
\]
for $t \in [0, \epsilon_1], d_{SE(3)}(y, R_n, (0, I)) < \epsilon_2$, for some $\epsilon_1, \epsilon_2 > 0$. Now set $h = t$, $(y, R_n) = e^h A$ with $A = \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i$ and take the limit $h \downarrow \theta$ then we have
\[
\frac{d}{dt}(\tilde{V}(0, 0) + \sum_{i \in \{1, 2, 4, 5\}} c_i^2 dR(A_i) \tilde{V}(0, 0) \leq \frac{2\eta - 1}{2\eta} | \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i| \approx \frac{2\eta - 1}{2\eta}
\]
where we applied Lemma 5 (which tells us that the constant $C$ in Lemma 3 can be set to 1 in the limiting case $h \downarrow \theta$). Now the left-invariant vector fields are given by the derivative of the right regular representation $A_i = dR(A_i)$ with $A_i|_{(0, I)} = A_i$ so we see that
\[
\frac{d}{dt} \tilde{V}(0, 0) + \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i \tilde{V}(0, 0) - \frac{2\eta - 1}{2\eta} \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i| \approx \frac{2\eta - 1}{2\eta}
\]
with $A = \sum_{i \in \{1, 2, 4, 5\}} c_i^2 A_i \in \text{Te}(SE(3))$ and $d\tilde{V}(\cdot, t) = \sum_{i = 1}^{5} A_i \tilde{V}(\cdot, t) dA^i \in (\text{Te}(SE(3)))^*$. Now by the final remark in Definition 9 and Lemma 1 we see that
\[
\frac{d}{dt} \tilde{V}(0, 0) + \left(\sum_{i \in \{1, 2, 4, 5\}} |c_i|^2 \right)^{\frac{1}{2\eta}} \leq \frac{2\eta - 1}{2\eta} \sum_{i \in \{1, 2, 4, 5\}} |c_i|^2 \approx \frac{2\eta - 1}{2\eta}
\]
As a result we conclude that the erosions Eq. (136) with morphological kernel (122) are the (unique) viscosity solutions of the Hamilton-Jacobi equations (135) on the contact manifold $(\mathbb{R}^3 \times S^2, dA^3)$.

\section*{C The Hamilton-Jacobi equation on $(\mathbb{R}^3 \times S^2, dA^3)$ and the propagation of geodesically equidistant surfaces in $\mathbb{R}^3 \times S^2$}

Recall from Figure 6 that our left-invariant erosions on $\mathbb{R}^3 \times S^2$ take place on the contact/sub-Riemannian manifold $(SE(3), dA^3, dA^6)$. On $(SE(3), dA^3, dA^6)$ we set the Lagrangian (for $\eta > \frac{1}{2}$)
\[
\mathcal{L}_\eta(\hat{c}(p), \dot{\hat{c}}(p)) = \frac{2\eta - 1}{2\eta} \frac{\left| \hat{c}^1(p) \right|^2 + \left| \hat{c}^2(p) \right|^2}{D^{11}} + \frac{\left| \hat{c}^4(p) \right|^2 + \left| \hat{c}^5(p) \right|^2}{D^{44}}
\]
expressed in the $(SE(3), dA^3, dA^6)$ arc-length parameter $p$ given by
\[
p(\tau) = 0 \int \sum_{i \in \{1, 2, 4, 5\}} \frac{D^{i\tau}}{i!} |(dA^i|_{\gamma(\tau)}, \dot{\gamma}(\tau))|^2 d\tau.
\]
yielding (analogous to the previous section) the well-defined metric on $(\mathbb{R}^3 \times S^2, dA^3)$ given by
\[
d((y, n), (y', n')) = d(((R_w)^T y - y'), ((R_w)^T n), (0, e_z)) = \frac{\max_p}{0} \int \mathcal{L}_\eta(\hat{c}(p), \dot{\hat{c}}(p)) dp.
\]
Let us return to the general Lagrangian minimization problem on \((\mathbb{R}^3 \times S^2, dA^3)\) for \(\eta > \frac{1}{2}\)

\[
E_\eta(y, n, t) := \inf_{\gamma = (s(\cdot), h_\gamma(\cdot)) \in C^\infty((0, p_{\text{max}}), SE(3)),
\gamma(0) = \eta, \gamma(t) = (y, n),
\langle \theta(A), \dot{\gamma}(t) \rangle = 0}
\int_0^{p_{\text{max}}=t} \mathcal{L}_\eta(\dot{\gamma}(p), \dot{\gamma}(p)) \, dp.
\]

(153)

for some given \(g_0 \in SE(3)\) and where the total arc-length \(p_{\text{max}}\) in \(\mathbb{R}^3 \times S^2\) is fixed.\(^{12}\) say \(p_{\text{max}} = t > 0\). Along an optimizing curve \(\gamma^*(t) = (x^*(t), n^*(t))\) in \(SE(3)\) with corresponding curve \(s \mapsto \gamma_s^*(t) = (x^*(s), n^*(s)) \in \mathbb{R}^3 \times S^2\) we have

\[
\frac{\partial}{\partial t} E_\eta(\gamma^*(t), t) = \mathcal{L}_\eta(\dot{\gamma}^*(t), \dot{\gamma}^*(t)).
\]

Now consider a family of surfaces associated to a smooth function \(W : \mathbb{R}^3 \times S^2 \times \mathbb{R}^+ \to \mathbb{R}^+\) given by

\[S_t := \{(y, n) \in \mathbb{R}^3 \times S^2 \mid W(y, n, t) = W_0\}\]

parameterized by \(t \geq 0\), where \(W_0 > 0\) is some positive constant. Such a family of surfaces is called \textit{geodesically equidistant},\(^{66}\) if

\[
\frac{dW}{dt}(\gamma^*(t), t) = \frac{\partial E_\eta}{\partial t}(\gamma^*(t), t) = \mathcal{L}_\eta(\dot{\gamma}^*(t), \dot{\gamma}^*(t)),
\]

\[
\langle dW(\cdot, t)|_{\gamma^*(t)}, \dot{\gamma}^*(t) \rangle = \nabla_{\dot{\gamma}} \mathcal{L}_\eta(\gamma^*(t), c)|_{c=\dot{\gamma}^*(t)}.
\]

(154)

The chain-law now gives

\[
\frac{\partial W}{\partial t}(\gamma^*(t), t) + \langle dW(\cdot, t)|_{\gamma^*(t)}, \dot{\gamma}^*(t) \rangle = \mathcal{L}_\eta(\dot{\gamma}^*(t), \dot{\gamma}^*(t)) \Leftrightarrow
\frac{\partial W}{\partial t}(\gamma^*(t), t) = -\mathcal{L}_\eta(\dot{\gamma}^*(t), \dot{\gamma}^*(t)) + \langle dW(\cdot, t)|_{\gamma^*(t)}, \dot{\gamma}^*(t) \rangle
\]

where according to the 2nd equality in (154) we may rewrite the righthand side as

\[
e^c := \sup_{c \in \gamma^*(t)} \left\{ -\mathcal{L}_\eta(\gamma^*(t), c) + \langle dW(\cdot, t)|_{\gamma^*(t)}, c \rangle \right\}
\]

which equals the Legendre-Fenchel transform of \(\mathcal{L}_\eta(\gamma^*(t), \cdot)\) on \(T_{\gamma^*(t)}(SE(3))\) that can be computed by the results in Appendix B, recall Def. 9 and Lemma 1 so that we obtain the Hamilton-Jacobi equation on \(\mathbb{R}^3 \times S^2\):

\[
- \frac{\partial W}{\partial t}(\gamma^*(t), t) = \frac{1}{2\eta} \left( \frac{G_1^{-1}(\gamma^*(t))}{\eta}(dW(\gamma^*(t), t), dW(\gamma^*(t), t)) \right) \eta \Leftrightarrow
\]

\[
- \frac{\partial W}{\partial t}(\gamma^*(t), t) = \frac{1}{2\eta} \left( D^{11}(A_1|_{\gamma^*(t)} W(\gamma^*(t), t))^2 + D^{11}(A_2|_{\gamma^*(t)} W(\gamma^*(t), t))^2 + D^{44}(A_4|_{\gamma^*(t)} W(\gamma^*(t), t))^2 + D^{44}(A_5|_{\gamma^*(t)} W(\gamma^*(t), t))^2 \right) \eta,
\]

along the characteristic curves. So we conclude that iso-contours of the solutions of \(W\) in Eq. 52 and Eq. 135 are (at least) locally geodesically equidistant. This allows us to use the Hamilton-Jacobi equations (135) for wavefront propagation methods\(^{61, 55}\) for finding geodesics in \(\mathbb{R}^3 \times S^2\). We will consider this in future work.

### D Asymptotical Expansions around the Origin of the \(k\)-step Time-integrated Heat Kernel on \(\mathbb{R}^3 \times S^2\)

Recall from Section 10.2 the Gaussian estimates for the heat-kernels (contour enhancement):

\[
K^{33, D^{44}}_t(y, n) = \frac{1}{16\pi^2(D^{33})^2(D^{44})^2 t^4} e^{-\frac{|x-y|^2 + |n|^2}{4t(D^{33})^2(D^{44})^2}},
\]

\(^{12}\)Otherwise for fixed \(\eta\) there does not exist a minimizer.
with \( |g| \) given by Eq. (87). Then we obtain the following relation (with again short notation \( g = (y, R_n) \in SE(3) \)):

\[
\begin{align*}
R_{\lambda,k}^{D^{33},D^{44}}(y,n) & := ((-D^{33}(A_3)^2 - D^{44}(A_4)^2 - D^{44}(A_5)^2 + \lambda I)^{-k} \delta_n) (y,n) \\
& = \int_0^\infty K_t^{D^{33},D^{44}}(y,n) \Gamma(t;k,\lambda) \, dt \\
& = \frac{1}{16\pi \sqrt{|D^{33}|} |D^{44}|} \int_0^\infty t^{k-3} e^{-\frac{|y|^2}{4t}} e^{-\lambda t} \, dt \\
& = \frac{2^{1-k}}{\pi (|D^{33}|)^{k-1}(k-1)!} |y|^{k-4} K_{4-k}(|y|\sqrt{\lambda})
\end{align*}
\]

with \( \Delta_{S^2} = A_3^2 + A_5^2 \) and now we have the following asymptotical formula for the Bessel functions

\[
K_\nu(z) \approx \begin{cases} 
-\log(z/2) - \gamma_{\text{EULER}} & \text{if } \nu = 0 \\
\frac{1}{2}(|\nu|-1)! \frac{1}{z^{\nu}} & \text{if } \nu \in \mathbb{Z}, \nu \neq 0.
\end{cases}
\]

with Euler’s constant \( \gamma_{\text{EULER}} \), which holds for \( 0 < z << 1 \), so that for \( |g| = |(y, R_n)| << 1 \) we have

\[
R_{\lambda,k}^{D^{33},D^{44}}(y,n) \approx \begin{cases} 
\frac{2 (-k+|\nu|-4)}{\pi (|D^{33}|)^{k-1}(k-1)!} |y|^{-|\nu|} (\lambda - \frac{2}{3})^{2-\lambda k} & \text{if } k \neq 4, \\
\frac{1}{\pi (|D^{33}|)^{k-1}(k-1)!} (-\log |y|\sqrt{\lambda} - \gamma_{\text{EULER}}) 2^{-\lambda k} & \text{if } k = 4
\end{cases}
\]

Likewise in the contour completion kernel, recall (82), we get rid of the singularity at the origin in

\[
R_{\lambda,k} = R_{\lambda,1} k^{-1} \Delta_{\mathbb{R}^3 \times S^2} R_{\lambda,1}
\]

by setting \( k \geq \dim(\mathbb{R}^3 \times S^2) = 5 \). In other words to avoid a singularity in the Green’s function one must use at least \( k = 5 \) iteration steps in the contour-enhancement process.

## E Conditions on a Left-invariant Metric Tensor on \( \mathbb{R}^3 \times S^2 \) and the Choice of \( D^{ij} \) and \( g^{ij} \)

In this section we derive sufficient conditions on a metric tensor (8) to be both left-invariant and well-defined on the quotient \( \mathbb{R}^3 \times S^2 = SE(3)/\{(0) \times SO(2)\} \).

**Definition 10** A metric tensor \( \tilde{G} : SE(3) \times T(SE(3)) \times T(SE(3)) \to \mathbb{C} \)

- is left-invariant iff
  \[
  \tilde{G}_{gq}(L_g \tilde{X}_q, L_g \tilde{Y}_q) = \tilde{G}_{q}(\tilde{X}_q, \tilde{Y}_q)
  \]
  for all \( g, q \in SE(3) \) and all \( \tilde{X}, \tilde{Y} \in T(SE(3)). \)
- provides a well-defined metric tensor on \( \mathbb{R}^3 \times S^2 = SE(3)/\{(0) \times SO(2)\} \) iff
  \[
  \tilde{G}_{gh}(R_h \tilde{X}_g, R_h \tilde{Y}_g) = \tilde{G}_{g}(\tilde{X}_g, \tilde{Y}_g)
  \]
  for all \( g \in SE(3) \) and all \( h \in \{(0) \times SO(2)\} \) and all \( \tilde{X}, \tilde{Y} \in T(SE(3)), \) in which case the corresponding metric tensor on the quotient is then given by
  \[
  G_{(y,n)}(\sum_i c^i A_i|_{(y,n)}), \sum_j d^j A_j|_{(y,n)}) := G_{(y,R_n)}(\sum_i c^i \tilde{A}_i|_{(y,R_n)}, \sum_j d^j \tilde{A}_j|_{(y,R_n)}).
  \]
where vector fields are described by the differential operators on $C^1(\mathbb{R}^3 \times S^2)$:

\[
(A_j)_{\|g,n\|} U(y, n) = \lim_{h \to 0} \frac{U(g+h R e_j, n) - U(g-h R e_j, n)}{2h},
\]

\[
(A_{3+j})_{\|g,n\|} U(y, n) = \lim_{h \to 0} \frac{U(g, (R_6 R e_j, h) R e_j, n) - U(g, (R_6 R e_j, -h) R e_j, n)}{2h}, \quad j = 1, 2, 3,
\]

where $R e_j$ denotes the counter-clockwise rotation around axis $e_j$ by angle $h$, with $e_1 = (1, 0, 0)^T$, $e_2 = (0, 1, 0)^T$, $e_3 = (0, 0, 1)^T$. Note that the choice of $R_n$ satisfying Eq. (9) does not affect Eq. (157) because of Eq. (156).

**Remark 7** In the other sections in this article, for the sake of simplicity, we do not distinguish between $\hat{X}$ and $X$. For example we write both $A_3|_{\|g,n\|} U$ and $A_3|_{\|g,R_n\|} U$.

Set $\hat{\mathbf{A}} = (\hat{A}_1, \ldots, \hat{A}_6)^T$ as a column vector of left-invariant vector fields on $SE(3)$, then one has the following identity

\[
\hat{\mathbf{A}} g h = Z_\alpha(R_h) \cdot \hat{\mathbf{A}} g = Z_\alpha \hat{\mathbf{A}} g,
\]

with $Z_\alpha \in SO(6)$ is given by Eq. (46), which is straightforwardly verified by Eq. (31) where we computed the left-invariant vector fields explicitly in Euler-angles. As the functions $U$ are invariant under right-multiplication with elements $(0, R e_\alpha) \in \{(0) \times SO(2)\}$ this yields the following identity

\[
(A_i)_{\|g h\|} (g h) = \sum_{j=1}^6 (Z_\alpha j)_{ij} (A_i)_{\|g\|} (g),
\]

for all $h = (0, R e_\alpha)$, where $Z_\alpha = R e_\alpha g + R e_\alpha g \in SO(6)$, with $R e_\alpha \in SO(3)$ is given by (46). Recall that by right multiplication with $(0, R e_\alpha)$ one takes a different section in the partition of left-cosets in $\mathbb{R}^3 \times S^2$, boiling down to a rotation over $\alpha$ simultaneously in the two grey planes depicted in Figure 6.

**Theorem 5** A metric tensor $G_{\|g,n\|} : (\mathbb{R}^3 \times S^2) \times T(\mathbb{R}^3 \times S^2) \times T(\mathbb{R}^3 \times S^2) \to \mathbb{R}$ given by

\[
G_{\|g,n\|} = \sum_{i,j=1}^6 g_{ij}(y, R_n) \, dA_i \otimes dA_j
\]

with $g_{6j} = g_{6} = 0$, $j = 1, \ldots, 6$ is well-defined and left-invariant iff

\[
Z_\alpha [g_{ij}] Z_\alpha^T = [g_{ij}], \quad \text{for all } \alpha \in [0, 2\pi), \quad \text{and}
\]

\[
g_{ij}(y, R_n) = g_{ij} \quad \text{are constant}
\]

which is satisfied iff

\[
[g_{ij}] = \text{diag}\{g_{11}, g_{11}, g_{33}, g_{44}, g_{44}, 0\}. \tag{159}
\]

**proof** The left-invariant vector fields satisfy $A_i|_{\|g q\|} = (L_g)^* A_i|_{\|q\|}$, since $(L_g)^* (L_q)^* = (L_{g q})^*$. So the left-invariance requirement reduces to

\[
L_g^* g_{ij} = g_{ij}
\]

for all $g \in SE(3)$. Now $SE(3)$ acts transitively onto $SE(3)$ (and onto $\mathbb{R}^3 \times S^2$) so $g_{ij}$ must be constant. Regarding (156) we note that

\[
G_{g h}((R_h)^* \sum_{i=1}^6 c^i \hat{A}_i|_{\|g\|}, (R_h)^* \sum_{j=1}^6 c^j \hat{A}_j|_{\|g\|}) = \sum_{i,j,k,l=1}^6 G_{g h} (c^k (Z_\alpha^T)_{ij}^l \hat{A}_k|_{\|g h\|}, (Z_\alpha^T)_{ij}^l \hat{A}_l|_{\|g h\|}) = \sum_{i,j=1}^6 (c^6 g_{ij})
\]

62
for all \((c^1, \ldots, c^6) \in \mathbb{R}^6\) and all \(\alpha \in [0, 2\pi)\) so that
\[
\forall \alpha \in [0, 2\pi) : Z_\alpha^T [g_{ij}] Z_\alpha = [g_{ij}] .
\]
The final results follows by Schur’s lemma on \(SO(2)\) (operators commuting with irreducible representations are multiples of the identity). \qed

The actual (horizontal) metric (induced by the metric tensor given by Eq. (10) on the contact manifold \((\mathbb{R}^3 \times S^2, \mathcal{d}A^3, \mathcal{d}A^2)\) is given by
\[
d(\mathbf{y}, \mathbf{n}, \mathbf{y}', \mathbf{n}') := d(R^T_{\mathbf{n}}(\mathbf{y} - \mathbf{y}'), R^T_{\mathbf{n}} \mathbf{n}, 0, e_z)
\]
with (horizontal) modulus given by
\[
d_{\mathbb{R}^3 \times S^2}(\mathbf{y}, \mathbf{n}, 0, e_z) = \inf \left\{ \gamma \in C^\infty([0, t), S^2(\mathcal{A})] \mid \langle \mathcal{d}A^i |_{\mathbf{g}(\gamma)}, \mathcal{d}A^j |_{\mathbf{g}(\gamma)} \rangle = 0 \right\}
\]

**Remark 8** When measuring the distance (Eq. (160) and (161)) between the cosets \([g_1] = g_1H\) and \([g_2] = g_2H\), with \(H = \{0\} \times SO(2)\) and \(g_i = (x_i, R_{e_z, \gamma} R_{e, \beta} R_{e_z, \alpha}), \ i = 1, 2\) one first determines the elements from both cosets with vanishing first Euler angle, i.e \((x_i, R_{e_z, \gamma} R_{e, \beta} R_{e_z, \alpha})\) and then compute the distance w.r.t. these elements in the full group where the connecting curves are not allowed to use the “illegal” \(A_0\)-directions. Note that this procedure leads to a well-defined metric on \((\mathbb{R}^3 \times S^2, \mathcal{d}A^3, \mathcal{d}A^2)\) despite taking the section. The condition \(\langle \mathcal{d}A^0 |_{\mathbf{g}(\gamma)}, \mathbf{\dot{g}(\gamma)} \rangle = 0\) avoids possible short-cuts via the “illegal” \(A_0\)-direction.

### E.1 Data adaption and left invariance

In the erosion algorithms one can include adaptivity by making \(D^{44}\) depend on the local laplace-Beltrami-operator, recall Subsection 7.1, whereas in the diffusion algorithms one can include adaptivity by replacing \(D^{33}\) in \(A_3 D^{33} A_3\) by a data adaptive conductivity
\[
D^{33}(U) = e^{-|A_3 U|^2/\lambda}, \ K > 0.
\]
In both cases this does **not** correspond to making a left-invariant adaptive inverse metric tensor, as this would contradict Theorem 5. However, an adaptive erosion generator (\(\eta = 1\)):
\[
U \mapsto \sum_{i,j=1}^5 g^{ij}(U)(y, n) \cdot (A_i \otimes A_j)(dU, dU) = \sum_{i,j=1}^5 g^{ij}(U)(y, n) \cdot (A_i U)(A_j U)
\]
is left-invariant iff \(g^{ij}\) is left-invariant, that is \(g^{ij}\) commutes with left regular action of \(SE(3)\) onto \(L_2(\mathbb{R}^3 \times S^2)\). Similarly an adaptive diffusion generator
\[
U \mapsto \sum_{i,j=1}^5 A_i (D^{ij}(U) A_j(U)),
\]
is left-invariant iff \(D^{ij}\) is left-invariant.

### F Putting the left-invariant vector fields and the diffusion generator in matrix form in case of linear interpolation

We will derive the \(N^3 N_o \times N^3 N_o\) matrix form of the **forward** approximation (100) of the left-invariant vector fields and subsequently for the (hypo)-elliptic left-invariant diffusion generator. Here \(N\) stands for the number of spatial
We approximate the spatial vector fields by
\[
(A_{p+3}U)(y, n_i) \approx \frac{U(y, n_i)}{h_a} - U(y, n_i),
\]
with
\[
(A_p U)(y, n_i) \approx \frac{U(y + h R_{n_i} e_z) - U(y)}{h_a},
\]
where the upper-index \( f \) stands for “forward” and with
\[
(A_{p+3} U)(y, n_i) \approx \frac{U(y + h R_{n_i} e_z) - U(y)}{h_a},
\]
\[
A_{p+3} := \frac{1}{h_a} \left( \bigoplus_{l=1}^{N_o} M^{f, h_a}_{p+3} - I_{N^3 N_o} \right),
\]
and where \( l \in \{1, \ldots, N_o\} \) enumerates the discrete orientations \( n_i \in S^2 \) and where \( y = (y^1, y^2, y^3) \in \{1, \ldots, N\}^3 \), where \( h \) denotes spatial step-size and \( h_a \) denotes angular stepsize.

We approximate the angular vector fields by
\[
\{H_{p,l}^h\}, \ldots, N^3_3 \}
\]
So if we store \( (U(y, n_i))_{p=1, \ldots, N_o} \) and \( y \in \{1, \ldots, N\}^3 \) in one long column vector \( y \in \mathbb{R}^{N^3 N_o} \) we can represent the (forward) angular left-invariant vector fields by the matrix
\[
A_f := \frac{1}{h_a} \left( \bigoplus_{l=1}^{N_o} M^{f, h_a}_{p+3} - I_{N^3 N_o} \right)
\]
with \( \bigoplus \) the Kronecker product and with \( M^{f, h_a}_{p+3} \in \mathbb{R}^{N^3 N_o \times N^3 N_o} \) the matrix with entries (162) and where \( I_{N^3 N_o} \in \mathbb{R}^{N^3 N_o \times N^3 N_o} \) denotes the identity matrix.

The (forward) spatial left-invariant vector fields is now represented by the block matrix
\[
A_f := \frac{1}{h_a} \left( \bigoplus_{l=1, \ldots, N_o} M^{f, h, l}_{p+3} - I_{N^3 N_o} \right)
\]
with \( M_{p}^{f,h,l} \in \mathbb{R}^{N_{3} \times N_{3}} \) the matrix with entries \( h^{-1} k_{p}^{f,h}[y^{2} - y^{1}, y^{2}, y^{3}] \).

Similarly, one defines central (index by \( c \)) and backward differences (index by \( b \)). The matrix-representation of the generator of the (hypo-)elliptic diffusion, Eq. (102), is now given by \( J_{SE} = J_{S^{2}} \in \mathbb{R}^{N_{3}N_{3}} \) with

\[
J_{SE} := D_{33} A_{3} A_{3} + D_{11} \left( A_{1} A_{1} + A_{2} A_{2} \right) ,
J_{S^{2}} := D_{44} \left( A_{4} A_{4} + A_{5} A_{5} \right) .
\]

(163)

\section{Solving (the Pfaffian system) for geodesics on \( SE(3), dA, dA^{2}, dA^{6} \)}

Here we follow the same approach as in [30, App.A] where we minimized on the contact manifold \( SE(2), dA_{SE(2)}^{3} \). We extend the manifold \( SE(3) \) into \( Z = SE(3) \times (\mathbb{R}^+) \times (\mathbb{R} \times (T(SE(3)))^* \) on which \( SE(3) \) acts as follows

\[
\eta_{y} = \left( y_{1}, y_{2}, y_{3}, R \right), \kappa, \sigma, (\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \lambda_{5}, \lambda_{6}) \rightarrow \left( g(y_{1}, y_{2}, y_{3}, R), \kappa, \sigma, \text{CoAd}_{g}(\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \lambda_{5}, \lambda_{6}) \right)
\]

where CoAd is the coadjoint action of \( SE(3) \) onto the dual tangent space \((T(SE(3)))^* \), where \( \kappa = \dot{x} - \kappa^{3} A_{1} + \kappa^{4} A_{2} \) and \( ds = \sigma dt = ||x'(t)|| dt \) represent curvature and arc-length \( s \) of the spatial \( \mathbb{R}^{3}\)-part of curves in \( SE(3) \), as by definition on this extended contact manifold \((Z, \theta^{1}, \ldots, \theta^{6})\) the following Pfaffian forms vanish

\[
\begin{align*}
\theta^{1} & := dA_{1} = 0 , \\
\theta^{2} & := dA_{2} = 0 , \\
\theta^{3} & := dA_{3} - \sigma dt = 0 , \\
\theta^{4} & := dA_{4} - \kappa^{1} \sigma dt = 0 , \\
\theta^{5} & := dA_{5} - \kappa^{2} \sigma dt = 0 , \\
\theta^{6} & := dA_{6} = 0 
\end{align*}
\]

(164)

The first five Pfaffian forms have to vanish in order to ensure that \( \gamma : [0, L] \rightarrow SE(3) \) yields a horizontal curve \( s \mapsto (x(s), n(s)) \) in \( \mathbb{R}^{3} \times S^{2} \) where the spatial tangent corresponds to point on the sphere, i.e.

\[
\dot{x}(s) = n(s) .
\]

(165)

The 6th Pfaffian form is imposed to avoid a spurious correspondence between horizontal curves \( \gamma = (x, R) \) in the sub-Riemannian manifold \((SE(3), dA_{1}, dA_{2}, dA_{3})\) to curves \((x, n)\) in \( \mathbb{R}^{3} \times S^{2} \) satisfying (165) via

\[
(x(s), n(s)) = (x(s), R(s)e_{z}) .
\]

To this end we recall that \( A_{6} U = 0 \) for all smooth \( U : SE(3) \rightarrow \mathbb{R} \) given by \( U(x, R) = U(x, Re_{z}) \) with \( U : \mathbb{R}^{3} \times S^{2} \rightarrow \mathbb{R} \) and \( (dA_{6}|_{\gamma} , \dot{\gamma}) = 0 \) excludes spurious curves in \( SE(3) \) by means of

\[
(x(s), R(s)) \mapsto (x(s), R(s)Re_{z_{s}} e) .
\]

with \( \dot{x} \neq 0 \), that would correspond to the same horizontal curves in \( \mathbb{R}^{3} \times S^{2} \), see Figure 22. Our goal is to solve for the minimizing curves of the optimization problem (115) on \((SE(3), dA_{1}, dA_{2}, dA_{6})\)

\[
\inf_{h_{1}, h_{2} \in \{0\} \times SO(2)} \gamma \in C^{\infty}(0, 1), SE(3)),
\begin{align*}
\gamma(0) & = e_{0} , \\
\gamma(1) & = e_{1} , \\
(dA_{1}|_{\gamma} , \dot{\gamma}) & = (dA_{2}|_{\gamma} , \dot{\gamma}) = (dA_{6}|_{\gamma} , \dot{\gamma}) = 0
\end{align*}
\]

\[
\int_{0}^{1} \sum_{i \in \{3, 4, 5\}} \frac{1}{D_{i}} |dA_{i}(\gamma(s))|^{2} \frac{ds}{ds}
\]

(166)

where we set \( D_{33} = \beta^{-1} \), \( s \) spatial arc-length, and \( D_{44} = D_{55} = 1 \), so that the equivalent problem on \( \mathbb{R}^{3} \) (recall Eq. (116)) is:

\[
\int_{0}^{L} \sqrt{||\kappa(s)||^{2} + \beta^{2}} ds
\]

(167)
where $s, L > 0$, and $\kappa(s)$ are respectively spatial arclength, total length, and curvature of the spatial part of the curve.

**Theorem 6** The stationary curves $s \mapsto x(s) \in \mathbb{R}^3$ that minimize

$$\int_0^L \sqrt{\kappa^2 + \beta^2} \, ds$$

with arclength parameter $s \in [0, L]$, curvature $\kappa$ and $\beta > 0$ and free length $L > 0$, subject to boundary conditions $x(0) = x_0 = 0 \in \mathbb{R}^3, \dot{x}(0) = n_0 = e_z \in S^2$ and $x(L) = x_1 \in \mathbb{R}^3, \dot{x}(L) = n_1 \in S^2$ coincide with the stationary curves $s \mapsto (x(s), \dot{x}(s)) \in \mathbb{R}^3 \times S^2$ of the variational problem (116) on $\mathbb{R}^3 \times S^2$ and they satisfy

$$\frac{d}{dt} \int_{N_i} \psi = 0 \text{ with } \psi = \sqrt{\|\kappa\|^2 + \beta^2} \sigma dt + \sum_{i=1}^6 \lambda_i \theta^i$$

with $ds = \sigma dt, \sigma = \|x'(t)\|$ for all horizontal curve $t \mapsto N_i$ perturbations on the extended 15-dimensional manifold $Z = SE(3) \times (\mathbb{R}^+)^3 \times (T(SE(3)))'$.

Along the the minimizing curves $\gamma = (g, \kappa^1, \kappa^2, \sigma, \lambda_1, \ldots, \lambda_6)$ in $Z$ the Lagrange-multipliers are given by

$$\lambda_1(s) = -\dot{\lambda}_5(s), \quad \lambda_2(s) = \dot{\lambda}_4(s), \quad \lambda_3(s) = \beta \sqrt{1 - (\lambda_4(s))^2 - (\lambda_5(s))^2},$$

$$\lambda_4(s) = z^1(s), \quad \lambda_5(s) = z^2(s), \quad \lambda_6 = 0,$$

expressed in the normalized curvature

$$z(s) = (z^1(s), z^2(s)) := \frac{1}{\sqrt{(\kappa(s))^2 + \beta^2}}(\kappa^1(s), \kappa^2(s)) = \cosh(\beta s) z(0) + \frac{\sinh(\beta s)}{\beta} z'(0),$$

with $\kappa = \sqrt{(\kappa^1)^2 + (\kappa^2)^2}$. They satisfy the following preservation-laws

$$(\lambda_1)^2 + (\lambda_2)^2 + (\lambda_3)^2 = c^2 \beta^2, \text{ (co-adjoint orbits)},$$

$$\beta^{-2}(\lambda_3)^2 + (\lambda_4)^2 + (\lambda_5)^2 = 1,$$

with $c > 0$ constant. The $SE(3)$-part $s \mapsto g(s)$ of the stationary curves in $Z$ is obtained by means of

$$\lambda(s) m(g^{-1})(s) = \lambda(0) m(g^{-1})(0) = \lambda(L) m(g^{-1})(L), \quad (168)$$
with row-vector \( \lambda = (\lambda_1, \ldots, \lambda_6) \) and where \( m : SE(3) \to \mathbb{R}^{6 \times 6} \) is the matrix group representation given by

\[
m(g) = \begin{pmatrix} R & \sigma_x R \\ 0 & R \end{pmatrix}, \quad \text{for all } g = (x, R) \in SE(3),
\]

(169)

with \( \sigma_x \in \mathbb{R}^{3 \times 3} \) such that \( \sigma_x y = x \times y \). The curvature and torsion magnitude of (the spatial part of) these stationary curves are given by

\[
\kappa(s) = \beta \frac{z(s)}{\sqrt{1 - z^2(s)}} \quad \text{and} \quad \tau(s) = \frac{\det(z_0 | z_0')}{z^3(s)}
\]

with \( z(s) = \sqrt{(z^1(s))^2 + (z^2(s))^2} = \|z(s)\| \) with constant \( z_0, z_0' \in \mathbb{R}^2, L > 0 \) such that

\[
x(L) = x_1 \text{ and } \dot{x}(L) = n_1.
\]

The spatial part \( s \mapsto x(s) \) of the curves \( s \mapsto g(s) \) can be obtained by integrating the Frenet formulas

\[
\begin{pmatrix}
T(s) \\
N(s) \\
B(s)
\end{pmatrix} =
\begin{pmatrix}
0 & \kappa(s) & 0 \\
-\kappa(s) & 0 & \tau(s) \\
0 & -\tau(s) & 0
\end{pmatrix}
\begin{pmatrix}
T(0) \\
N(0) \\
B(0)
\end{pmatrix} +
\begin{pmatrix}
e_x \\
\frac{(z_0)_1 e_x - (z_0)_2 e_y}{\|z_0\|} \\
\frac{(z_0)_1 e_x + (z_0)_2 e_y}{\|z_0\|}
\end{pmatrix}
\]

where again \( s \in [0, L] \), denotes arclength parametrization of the spatial part of the curve with initial condition

\[
\begin{pmatrix}
T(0) \\
N(0) \\
B(0)
\end{pmatrix} =
\begin{pmatrix}
\frac{e_x}{2} \\
\frac{(z_0)_1 e_x - (z_0)_2 e_y}{\|z_0\|} \\
\frac{(z_0)_1 e_x + (z_0)_2 e_y}{\|z_0\|}
\end{pmatrix}
\]

If these curves are a global minimizer then they coincide with the geodesics on the sub-Riemannian manifold \((SE(3), dA^1, dA^2, dA^6)\) subject to left-invariant metric

\[
G_\beta = \beta^2 dA^3 \otimes dA^3 + dA^4 \otimes dA^4 + dA^5 \otimes dA^5.
\]

**Proof** We follow the general theory on optimizing Lagrangians on contact manifolds, \([13, 12]\) and we set the 1-form on \( Z \)

\[
\psi = \sqrt{\|\kappa\|^2 + \beta^2} \sigma dt + \sum_{i=1}^6 \lambda_i \theta^i
\]

where we must first find the Lagrange-multipliers. Now suppose we have a 1-parameter family of Legendre submanifolds \( \{N_\epsilon\}_{\epsilon \in \mathbb{R}} \) within \( Z \), this corresponds to a one parameter family of horizontal vector fields on \((SE(3))\). Then compute the variation of the integrated Lagrangian-form \( \psi \) along \( N_\epsilon \):

\[
\frac{d}{dt} \int_{N_\epsilon} \psi = \int_{N_\epsilon} \frac{\partial}{\partial t} |d\psi| + \int_{N_\epsilon} d\left( \frac{\partial}{\partial t} |d\psi| \right) = \int_{N_\epsilon} \frac{\partial}{\partial t} |d\psi|
\]

where we used the well-known Stokes Theorem \( \int_{N_\epsilon} d(\frac{\partial}{\partial t} |d\psi|) = \oint_{\partial N_\epsilon} \frac{\partial}{\partial t} |d\psi| = 0 \) and the formula for Lie derivatives of volume forms along vector fields \( \mathcal{L}_X A = X[dA + d(X|A)]. \) Consequently, the optimal/characteristic curves are entirely determined by

\[
\gamma'(s) \cdot |d\psi|_{\gamma(s)} = 0 \quad \text{for all } s > 0.
\]

But this by definition of the insert operator \( | \) means that \( d|_{\gamma'}(\gamma', v) = 0 \) for all \( v \in T(Z) \), or equivalently formulated

\[
(v) \cdot |d\psi|_{\gamma} = 0 \quad \text{for all } v \in T(Z).
\]

(170)

For further details see \([12]\). So in order to find the optimal trajectories one has to integrate the Pfaffian system

\[
v | d\psi = 0 \quad \text{for all } v \in T(Z),
\]

(171)
consisting of 15 vanishing dual forms.

Now by Cartan’s structural formula we have

\[ d(dA^k) = - \sum_{i,j=1}^{6} c^k_{ij} dA^i \otimes dA^j, \]

where \( c^k_{ij} \) are the structure constants of the Lie-algebra \( \mathcal{L}(SE(3)) \), recall Eq. (28) and using this crucial identity one finds after some straightforward (but intense) computation the following explicit form of (171):

\[
\begin{align*}
\partial_\kappa |d\psi &= (\sqrt{||\kappa||^2 + \beta^2} - \lambda_3 - \lambda_4 \kappa - \lambda_5 \lambda_2) \sigma dt = 0, \\
\partial_{\kappa^1} |d\psi &= (\kappa^1 / \sqrt{||\kappa||^2 + \beta^2} - \lambda_4) \sigma dt = 0, \\
\partial_{\kappa^2} |d\psi &= (\kappa^2 / \sqrt{||\kappa||^2 + \beta^2} - \lambda_5) \sigma dt = 0, \\
-\mathcal{A}_1 |d\psi &= d\lambda_1 - \lambda_2 dA^6 + \lambda_3 dA^5 = 0, \\
-\mathcal{A}_2 |d\psi &= d\lambda_2 + \lambda_4 dA^6 - \lambda_3 dA^5 = 0, \\
-\mathcal{A}_3 |d\psi &= d\lambda_3 - \lambda_4 dA^5 + \lambda_2 dA^6 = 0, \\
-\mathcal{A}_4 |d\psi &= d\lambda_4 - \lambda_5 dA^6 + \lambda_5 dA^5 - \lambda_2 dA^3 + \lambda_3 dA^2 = 0, \\
-\mathcal{A}_5 |d\psi &= d\lambda_5 - \lambda_6 dA^4 + \lambda_5 dA^6 - \lambda_3 dA^1 + \lambda_1 dA^3 = 0, \\
-\mathcal{A}_6 |d\psi &= d\lambda_6 - \lambda_4 dA^5 + \lambda_5 dA^4 - \lambda_1 dA^2 + \lambda_2 dA^1 = 0,
\end{align*}
\]

where in the last three Pfaffian forms in the left column one may set \( dA^1 = dA^2 = 0 \). Now by Noether’s Theorem the characteristic curves in \( Z \) are contained within the co-adjoint orbits, cf.[13]. As the adjoint action is given by push-forward of conjugation \( Ad(g) = (L_g R_{g^{-1}})_* \),

\[ Ad(g) A_i = (R_{g^{-1}})_* A_i |_g = (R_{g^{-1}})_* \sum_{i=1}^{3} c^i(g) \partial y^i |_g = 3 \sum_{i=1}^{3} c^i(g) \partial y^i |_e \]

with \((v^1)^2 + (v^2)^2 + (v^3)^2 = 1\), where we used \( \mathcal{A}_i |_g = (L_g)_{*} A_i \) and as the coadjoint action given by

\[ (\text{CoAd}(g)) \sum_{i=1}^{6} \lambda_i dA^i, \sum_{j=1}^{3} c^j A_j) = (\sum_{i=1}^{6} \lambda_i dA^i, \text{Ad}(g^{-1}) \sum_{j=1}^{3} c^j A_j) \]

acts transitively on the span by the dual angular generators we see that \( SE(3) \) co-adjoint orbits are given by

\[(\lambda_1)^2 + (\lambda_2)^2 + (\lambda_3)^2 = C^2,\]

\( C > 0 \). Indeed it directly follows from (171) that \( \sum_{i=1}^{3} \lambda_i d\lambda_i = 0 \). The first three Pfaffian forms in (171) yield

\[
\begin{align*}
\lambda_3 &= \frac{\beta^2}{\sqrt{||\kappa||^2 + \beta^2}}, \\
\lambda_4 &= \frac{\kappa^1}{\sqrt{||\kappa||^2 + \beta^2}}, \\
\lambda_5 &= \frac{\kappa^2}{\sqrt{||\kappa||^2 + \beta^2}}, \\
\lambda_1 &= \lambda_5 = -\lambda_3, \\
\lambda_2 &= \lambda_4 = \lambda_5, \\
\lambda_6 &= \lambda_4 \kappa - \lambda_5 \lambda_2 = 0, \quad \lambda_6 \text{ is constant.}
\end{align*}
\]

so that another preservation law is given by

\[ \beta^{-2}(\lambda_3)^2 + (\lambda_4)^2 + (\lambda_5)^2 = 1, \]

and as \( \dot{\lambda}_6 = \lambda_4 \kappa^2 - \lambda_5 \lambda_2 = 0, \) \( \lambda_6 \) is constant. Now since \( dA^6 = 0 \) is an extra constraint (recall Figure 22) that allows us to choose convenient representatives in the cosets, the minimizers on the quotient space do not depend on this constraint. Therefore\(^{13}\) we can set \( \lambda_6 = 0 \) and we find

\[
\dot{\lambda}_5 + \lambda_1 = 0 \Rightarrow \dot{\lambda}_5 + \dot{\lambda}_1 = \dot{\lambda}_5 - \frac{\beta^2 \kappa}{\sqrt{||\kappa||^2 + \beta^2}} = \dot{\lambda}_5 - \beta^2 \lambda_5 = 0,
\]

\(^{13}\)Comparison to an alternative derivation generalizing the approach in [53] on \( \mathbb{R}^2 \) to \( \mathbb{R}^3 \) confirmed this choice.
so that $\bar{\lambda}_5 = \beta^2 \lambda_5$. Analogously one finds $\bar{\lambda}_4 = \beta^2 \lambda_4$, so similar to the $(SE(2), d\mathcal{A}^3)$-case one has

$$\vec{z}(s) = \beta^2 z(s), \quad \text{with } z(s) = \frac{1}{\sqrt{\|\kappa(s)\|^2 + \beta^2 \kappa(s)}},$$

(174)

for the normalized curvature $z(s)$. Furthermore we find

$$\lambda_1 = -\lambda_3 \kappa^2 \text{ and } \lambda_2 = \lambda_3 \kappa^1.$$

So again in contrast to the common and well-known elastica the geodesics do not involve special functions and we have

$$z(s) = \cosh(\beta s) z(0) + \frac{\sinh(\beta s)}{\beta} z'(0).$$

(175)

Next we compute curvature magnitude and torsion magnitude. Curvature magnitude is given by

$$\kappa = \sqrt{(\kappa^1)^2 + (\kappa^2)^2}.$$

In order to compute the torsion, we compute the normal and binormal from the tangent

$$T(s) = A_3|_{\gamma(s)}.$$

When taking derivatives one should use covariant derivatives, recall Theorem 3 to compute

$$\frac{d}{ds} A_i|_{\gamma(s)} = \nabla_{\gamma(s)} A_i = \sum_{k,j=1}^6 c_{ij}^k \langle d\mathcal{A}^j |_{\gamma(s)}, \gamma(s) \rangle A_k |_{\gamma(s)}.$$

More explicitly this yields

$$\frac{d}{ds} A_1|_{\gamma(s)} = \kappa^2(s) A_1|_{\gamma(s)} - \kappa^1(s) A_2|_{\gamma(s)},$$

$$\frac{d}{ds} A_2|_{\gamma(s)} = \kappa^1(s) A_1|_{\gamma(s)} + \kappa^2(s) A_2|_{\gamma(s)},$$

(176)

$$\frac{d}{ds} A_3|_{\gamma(s)} = \kappa^1(s) A_3|_{\gamma(s)}.$$

along the horizontal optimal curves in $SE(3)$, where we used (164). Using (176) we find

$$T'(s) = \kappa^2(s) A_1 - \kappa^1(s) A_2,$$

$$N(s) = \frac{1}{\sqrt{(\kappa^1(s))^2 + (\kappa^2(s))^2}} \left( \kappa^2(s) A_1 - \kappa^1(s) A_2, \right),$$

$$N'(s) = \left( \frac{\kappa^2(s)}{\sqrt{(\kappa^1(s))^2 + (\kappa^2(s))^2}} \right)' A_1|_{\gamma(s)} - \left( \frac{\kappa^1(s)}{\sqrt{(\kappa^1(s))^2 + (\kappa^2(s))^2}} \right)' A_2|_{\gamma(s)} + \left( \frac{\kappa^1(s)}{\sqrt{(\kappa^1(s))^2 + (\kappa^2(s))^2}} \right)' A_3|_{\gamma(s)}$$

$$B(s) = \frac{1}{\sqrt{(\kappa^1(s))^2 + (\kappa^2(s))^2}} (\kappa^1(s) A_1 + \kappa^2(s) A_2).$$

Now the Frenet-frame satisfies $\vec{N} = -\kappa T + \tau B$ so curvature magnitude and torsion magnitude are given by

$$\kappa = \sqrt{(\kappa^1)^2 + (\kappa^2)^2} \text{ and } \tau = \frac{\kappa^1 \kappa^2 - \kappa^2 \kappa^1}{\kappa^2} = \frac{z^1 \dot{z}^2 - z^2 \dot{z}^1}{(z^1)^2 + (z^2)^2}.$$ 

(177)

So if we write $\|z\| = \sqrt{(z^1)^2 + (z^2)^2}$ we see that

$$\kappa = \beta \frac{\|z\|}{\sqrt{1 - \|z\|^2}} \text{ and } \tau = \frac{\det(z_0 | z'_0)}{\|z\|^2}.$$ 

(178)
where \( z_0 = z(0) \in \mathbb{R}^2 \) and \( z'_0 = z'(0) \in \mathbb{R}^2 \) and where we note that \( z^1 \) and \( z^2 \) satisfy the same linear ODE with (constant) Wronskian

\[
z^1(s)z^2(s) - z^2(s)z^1(s) = z^1(0)z^2(0) - z^2(0)z^1(0) = \det(z_0 | z'_0).
\]

We verified our results by extending Mumford’s approach to elastica on \( \mathbb{R}^2 \) to curves minimizing \( \int_0^L \sqrt{\kappa^2(s) + \beta^2} ds \) with \( L \) free on \( \mathbb{R}^3 \). The details will follow in future work. For now we mention that such approach finally results in the following non-linear ODE’s for \( \kappa \) and \( \tau \):

\[
\|z\|'' = (\beta^2 + \tau^2)\|z\| \quad \text{and} \quad 2\tau\|z\|'' + \tau'\|z\| = 0.
\]  

(179)

It can be verified that the linear ODE’s Eq. (174) and Eq. (178) indeed imply Eq. (179). So, besides of all the preservation-laws, we see another advantage of the symplectic differential geometrical approach on the extended manifold 15 dimensional manifold \( Z \) over the more basic approach on \( \mathbb{R}^3 \). Another advantage of the symplectic differential geometrical approach is the Frenet frame integration. Basically, one has to integrate

\[
\begin{pmatrix}
T(s) \\
N(s) \\
B(s)
\end{pmatrix} =
\begin{pmatrix}
0 & \kappa(s) & 0 \\
-\kappa(s) & 0 & \tau(s) \\
0 & -\tau(s) & 0
\end{pmatrix}
\begin{pmatrix}
T(0) \\
N(0) \\
B(0)
\end{pmatrix}
\]

(180)

where again \( s \in [0, L] \) denotes arclength parametrization of the spatial part of the curve with initial condition

\[
\begin{pmatrix}
T(0) \\
N(0) \\
B(0)
\end{pmatrix} = \begin{pmatrix}
\frac{1}{\|z_0\|} \left( (z_0)_2 e_x - (z_0)_1 e_y \right) \\
\frac{1}{\|z_0\|} \left( (z_0)_1 e_x + (z_0)_2 e_y \right)
\end{pmatrix}
\]

where we recall that the angles in the second chart \( \tilde{\beta}_0, \tilde{\gamma}_0 \) can be computed from \( n_0 \) by means of Eq. (111). Now everything is expressed in the five constants

\[
L, z_0 = ((z_0)_1, (z_0)_2)^T \quad \text{and} \quad z'_0 = ((z'_0)_1, (z'_0)_2)^T,
\]

which yield five degrees of freedom needed to meet the boundary condition

\[
x(L) = x_1 \in \mathbb{R}^3 \quad \text{and} \quad \dot{x} = n_1 \in S^2.
\]

Now in order to investigate on how the length \( L \) and the integration constants \( z_0 \) and \( z'_0 \) depend on the boundary condition, we follow a similar approach as in [30, App.A] where we managed to obtain full control over the equivalent\(^\text{14}\) problem in \( SE(2) \). To this end we re-express the last 6 Pfaffian forms in (172) as

\[
d\lambda = -\lambda m(g)^{-1} dm(g),
\]

(181)

where we recall (169), where \( m : SE(3) \to \mathbb{R}^{6 \times 6} \) forms a (uncommon) group representation as we will show next. Taking the outer product \( y \mapsto \sigma_y = x \times y \) is tensorial with respect to rotations and \( \sigma_{Rx} = R \sigma_y R^{-1} \) indeed implies

\[
m(g_1, g_2) = m(g_1) m(g_2) \quad \text{and} \quad m(e) = I
\]

for all \( g_1, g_2 \in SE(3) \). The identity (181) follows from Eq. (172) by means of

\[
m(g)^{-1} dm(g) = \begin{pmatrix}
R^{-1} dR & R^{-1} \sigma R \\
0 & R^{-1} dR
\end{pmatrix} = \begin{pmatrix}
R^{-1} dR & -\sigma R^{-1} d\xi \\
0 & R^{-1} dR
\end{pmatrix}
\]

and recall from Eq. (33) that \( R^{-1} d\xi = (dA^1, dA^2, dA^3)^T \) and where the matrix \( g^{-1} dg \) contains \( \omega_{ij}^k = \sum_i c_{ij}^k dA_i \), recall Theorem 3, as elements. Now from (181) we deduce that

\[
d(\lambda m(g)^{-1}) = \lambda dm(g)^{-1} + (d\lambda)(m(g))^{-1} = (\lambda m(g))^{-1} dm(g) + d\lambda m(g)^{-1} = 0
\]

and the result (168) follows.

\(^\text{14}\)In [30, App.A] we had to choose \( z_0 \) and \( z'_0 \) and \( L \) such that \( x(L) = x_1 \in \mathbb{R}^2 \) and \( \dot{x}(L) = n_1 \in S^1 \).
Theorem 7 The Frenet system (180) for the stationary curves can be integrated analytically. By means of Eq. (168) we find
\[ m(g) = h_0^{-1}m(\tilde{g}), \quad g = (x, y, z, R), \]
where \( h_0^{-1} \in SE(3) \) is given by
\[ h_0^{-1} = \begin{pmatrix} R_0^T & 0 \\ -\sigma R_0^T & R_0 \end{pmatrix}, \]
where \( x_0 = (\bar{x}_0, \bar{y}_0, \bar{z}_0) \in \mathbb{R}^3 \) and \( R_0 \in SO(3) \) given by
\[ \bar{x}_0 = 0 \ (\text{free}), \quad \bar{y}_0 = \frac{W}{c\sqrt{\beta^2 - ||z_0'||^2}}, \quad \bar{z}_0 = \frac{z_0'}{c\sqrt{||z_0'||^2}}. \]

with Wronskian \( W = z_1(0)z_2(0) - z_2(0)z_1(0) = z_1(0)z_2(0) - z_2(0)z_1(0) \)
and \( \tilde{z}_0 = (z_0')_1 )_2 \) if \( z_0' \neq 0 \). In case \( z_0' = 0 \) we have
\[ \bar{x}_0 = -\frac{1}{c\beta} \begin{pmatrix} 0 \\ (z_0)_1 \\ (z_0)_2 \end{pmatrix} \text{ and } R_0 = R_{e_\gamma, z} \]
Furthermore, we have
\[ \hat{g}(s) = (\hat{x}(s), \hat{R}(s)) = (\hat{x}(s), \hat{y}(s), \hat{z}(s), \hat{R}(s)) \]
for all \( s \in [0, L] \) with
\[ \hat{x}(s) = \hat{x}(0) - \frac{i\sqrt{2\gamma}}{\sqrt{1 + c\gamma}} (E ((\beta s + \frac{\xi}{2}), m) - E ((\frac{\xi}{2}), m)), \]
\[ (\hat{y}(s), \hat{z}(s))^T = \begin{pmatrix} (z_0)_1 \\ (z_0)_2 \end{pmatrix} \]
\[ \begin{pmatrix} 0 \\ \tau \end{pmatrix} = \begin{pmatrix} 0 \\ \tau \end{pmatrix} \]
\[ A(s) = \begin{pmatrix} \frac{z(s) \cdot \hat{z}(s)}{||z(s)||^2} & -\frac{W}{c\beta} \sqrt{\beta^2 - ||z(s)||^2} \\ \frac{W}{c\beta} \sqrt{\beta^2 - ||z(s)||^2} & \frac{z(s) \cdot \hat{z}(s)}{||z(s)||^2} \end{pmatrix} \]
and \( \hat{R}(s) \) in \( SO(3) \) such that
\[ (\hat{R}(s)e_z, n(s) = (\hat{x}(s), (A(s)(\hat{y}(s), \hat{z}(s))^T)^T) = \begin{pmatrix} \lambda_3(s) \\ \lambda_4(s) \end{pmatrix} \quad \begin{pmatrix} \frac{z(s)}{||z(s)||} \end{pmatrix} \]

Proof With respect to Eq. (182),(183), (184), (185) and (186) we note that by means of Eq. (168) we have
\[ \lambda(m(g))^{-1} = \mu \Leftrightarrow \lambda = \mu m(g) = \mu h_0^{-1}m(\tilde{g}) = \lambda(0)(m(g(0)))^{-1}h_0^{-1}m(\tilde{g}) = \lambda(0)h_0^{-1}m(\tilde{g}) \]
as \( g(0) = (0, I) \in SE(3) \) implies that its corresponding matrix representation equals the \( 6 \times 6 \)-identity matrix 
\( m(g(0)) = I_6 \). Then we choose \( h_0^{-1} \) such that
\[
\mu h_0^{-1} = \lambda(0) h_0^{-1} = (c\beta, 0, 0, -\frac{W}{c\beta}, 0, 0)
\]
with \( \mu_i = \lambda_i(0), i = 1, \ldots, 6 \), which follows from the previous theorem. As a result \( h_0 \) now follows from
\[
h_0^{-T} \begin{pmatrix}
\mu_1 \\
\mu_2 \\
\mu_3 \\
\mu_4 \\
\mu_5 \\
\mu_6
\end{pmatrix} = \begin{pmatrix}
c\beta \\
0 \\
0 \\
-\frac{W}{c\beta} \\
0 \\
0
\end{pmatrix} \Leftrightarrow \begin{pmatrix}
R_0 \\
\sqrt{c^2\beta^2 - \Vert z_0 \Vert^2} \\
\mathbb{F}_0 \times \begin{pmatrix}
0 \\
0 \\
0 
\end{pmatrix} + R_0 \\
\begin{pmatrix}
(z_0)_1 \\
(z_0)_2 \\
0
\end{pmatrix} = \begin{pmatrix}
cia \\
0 \\
0 
\end{pmatrix} \right)
\]
(187)

Next we shall derive the ODE for \((\dot{g}, \dot{z})\). We parameterize by \( \tilde{R} = R_{e_x, \tilde{\gamma}} R_{e_y, \beta} R_{e_z, \tilde{\alpha}} \in SO(3) \) and substitution of this parametrization in
\[
\lambda = \mu h_0^{-1} m(\tilde{g}) = (c\beta, 0, 0, -\frac{W}{c\beta}, 0, 0) m(\tilde{g}),
\]

yields the system
\[
\tilde{R} \begin{pmatrix}
\lambda_1 \\
\lambda_2 \\
\lambda_3
\end{pmatrix} = \begin{pmatrix}
c\beta \\
0 \\
0
\end{pmatrix} \right)
\]
(188)

and the system
\[
\frac{1}{c\beta} R_{e_x, \tilde{\gamma}} \begin{pmatrix}
\sqrt{\lambda_1^2 + \lambda_2^2} & 0 & \lambda_3 \\
0 & c\beta & 0 \\
-\lambda_3 & 0 & \sqrt{\lambda_1^2 + \lambda_2^2}
\end{pmatrix} \left( \begin{pmatrix}
\lambda & \lambda_2 \\
\lambda_2 & 1 \\
0 & 0
\end{pmatrix} \right) = \begin{pmatrix}
\lambda_4 \\
\lambda_5 \\
0
\end{pmatrix} \right)
\]
(189)

where we used \( \tilde{\beta} = \arg(\sqrt{\lambda_1^2 + \lambda_2^2} + i\lambda_3) \) and \( \tilde{\alpha} = \arg(\lambda_1 - i\lambda_2) \) that follow by Eq. (188). Taking the derivative with respect to spatial arc-length \( s \) in system (189) yields
\[
\frac{d}{ds} \tilde{R}(\lambda(2)) = \tilde{R}(\lambda(2)) + \dot{\tilde{R}}(\lambda(2)) = \tilde{R}(\lambda(2)) = c\beta \begin{pmatrix}
0 \\
-\tilde{z}
\end{pmatrix}, \text{ with } \lambda(2) = (\lambda_4, \lambda_5, 0),
\]

where we stress that
\[
\tilde{R}^T d\tilde{R} = \sigma_{(d, A^1, d, A^2, 0)} = \sigma_{(\kappa, d), \kappa^2 d^2, 0} \Rightarrow
\]
\[
\dot{\tilde{R}}(\lambda(2))^T = \tilde{R} \sigma_{(\kappa, \kappa^2, 0)} \begin{pmatrix}
\kappa^1 \\
\kappa_5 \\
0
\end{pmatrix} \times \begin{pmatrix}
\kappa^1 \\
\kappa_5 \\
0
\end{pmatrix} = \begin{pmatrix}
1 \\
\sqrt{(\kappa^1)^2 + (\kappa^2)^2 + \beta^2}
\end{pmatrix} = 0.
\]

As a result, since \( \sqrt{(\lambda_1)^2 + (\lambda_2)^2} = \Vert z \Vert \), we obtain
\[
\dot{\tilde{z}} = \frac{\cos \tilde{\gamma} \Vert z \Vert}{c\beta} \text{ and } \dot{\tilde{y}} = -\frac{\sin \tilde{\gamma} \Vert z \Vert}{c\beta}
\]
(190)

whereas (189) yields
\[
\begin{pmatrix}
-\frac{\epsilon \tilde{z}}{\Vert z \Vert} \cos \tilde{\gamma} - \frac{W}{c\beta} \sqrt{c^2\beta^2 - \Vert z \Vert^2} \sin \tilde{\gamma} = -c\beta \tilde{z}, \\
-\frac{\epsilon \tilde{z}}{\Vert z \Vert} \sin \tilde{\gamma} + \frac{W}{c\beta} \sqrt{c^2\beta^2 - \Vert z \Vert^2} \cos \tilde{\gamma} = c\beta \tilde{y}
\end{pmatrix}
\]
from which we deduce that
\[
(A(s))^{-1} \begin{pmatrix}
\tilde{y}(s) \\
\tilde{z}(s)
\end{pmatrix} = \begin{pmatrix}
\tilde{y}(s) \\
\tilde{z}(s)
\end{pmatrix} \Leftrightarrow \begin{pmatrix}
\dot{\tilde{y}}(s) \\
\dot{\tilde{z}}(s)
\end{pmatrix} = A(s) \begin{pmatrix}
\dot{\tilde{y}}(s) \\
\dot{\tilde{z}}(s)
\end{pmatrix}.
\]

As the matrices $A(s)$ share the same eigen-vectors ($(i,1)^T$ and $(-i,1)^T$) they commute and we have

$$
\begin{align*}
\left( \begin{array}{c}
\tilde{y}(s) \\
\tilde{z}(s)
\end{array} \right) &= e^{s} A(s) \left( \begin{array}{c}
\tilde{y}(0) \\
\tilde{z}(0)
\end{array} \right) = \frac{1}{2i} (\tilde{y}(0) + i\tilde{z}(0)) e^{s} \left( \begin{array}{c}
i \\
1
\end{array} \right) \\
&\quad + \frac{1}{2i} (\tilde{y}(0) + i\tilde{z}(0)) e^{s} \left( \begin{array}{c}i \\
1
\end{array} \right)
\end{align*}
$$

where the latter two vectors are each other’s conjugate. Finally, $\tilde{x}(s)$ follows by integration

$$
\tilde{x}(s) = \tilde{x}(0) + \int_{0}^{s} \frac{e^{s}}{c^2} \mathrm{d}r = \tilde{x}(0) + \frac{e^{s}}{c} \sqrt{1 - \|(\tau)\|^2} \mathrm{d}r
$$

with $c_1 = \frac{1}{(1+c^2)} (\|z_0\|^2 - \|z_0'\|^2)$, $c_2 = \frac{2}{\beta(1+c^2)} \theta_0 \cdot \tilde{z}_0$, $m = \frac{2\gamma}{\gamma^2}$, which can be expressed as

$$
\tilde{x}(s) = \tilde{x}(0) + \frac{\sqrt{1+c^2}}{c} \int_{0}^{s} \sqrt{1 - \gamma \cos(2\beta \tau + i\varphi)} \mathrm{d}r
$$

where $\varphi = \frac{1}{2} \log \frac{c_1+c_2}{c_1-c_2}$, $v = i\beta \tau$, $\gamma = \sqrt{(c_1)^2 - (c_2)^2}$ and where we note that

$$
\gamma = \frac{1}{1+e^2} \|z_0 - \beta^{-1}z_0\| \|z_0 + \beta^{-1}z_0\| \leq \frac{1}{1+e^2} \frac{1}{2} \left( \|z_0 - \beta^{-1}z_0\|^2 + \|z_0 + \beta^{-1}z_0\|^2 \right) = \frac{1-e^2}{1+e^2} \leq 1.
$$

Corollary 3 The solution curves stay in a plane iff $z_0$ and $z_0'$ are linear dependent, i.e. $W = \det(z_0, z_0') = 0$. In the special case $z_0' = -\beta z_0$, ($c = 1$ and $W = 0$) we find

$$
\tilde{x}(s) = \tilde{x}(0) + s + \frac{1}{c^2} \left( \sqrt{1 - \|z_0\|^2} - \sqrt{1 - \|z_0\|^2} e^{-2s\beta} + \log \left( \frac{1+\sqrt{1-\|z_0\|^2} e^{-2s\beta}}{1+\sqrt{1-\|z_0\|^2}} \right) \right),
$$

$$
(\tilde{y}(s), \tilde{z}(s))^T = e^{-\beta s} (\tilde{y}(0), \tilde{z}(0))^T
$$

In the case where solution curves stay in the plane, i.e. $W = 0$, with general $c$, we find

$$
\tilde{x}(s) = \tilde{x}(0) + \frac{1}{c} \int_{0}^{s} \sqrt{1 - \|z_0\|^2} \mathrm{d}r,
$$

$$
\tilde{y}(s) = 0
$$

and

$$
\tilde{z}(s) = \begin{cases} 
\tilde{z}(0) \|\tilde{z}(0)\| \|\tilde{z}(0)\| & \text{for } c \leq 1 \\
\operatorname{sgn}(s_0 - s) \tilde{z}(0) \|\tilde{z}(0)\| & \text{for } c > 1
\end{cases}
$$

where $z(s)$ is given by Eq. (175) and $s_0 = \frac{1}{2\beta} (\ln(\|z_0'\|^2 - \beta^2 z_0'^2) - \ln(\|z_0' + \beta z_0\|^2))$ so that $\|z(s_0)\| = 0$. These solutions indeed coincide with the geodesics on the contact manifold $(SE(2) \equiv \mathbb{R}^2 \times S^1, -\sin \theta dx + \cos \theta dy)$ where elements are parameterized by $(x, y, e^{i\theta})$, cf. [33, App.A].

See Figure 23 for an example of a geodesic with $W = 0$ and $c = 1$. 

73
Figure 23: Example of a geodesic in $\mathbb{R}^3 \times S^2$. Left: $s \mapsto \tilde{x}(s)$. Right: $s \mapsto x(s)$. Parameter settings $\beta = \frac{1}{10}$, $z_0 = (\frac{1}{2}, 0)^T$, $z'_0 = -\beta z_0$, (so $c = 1$ and $W = 0$), length $L = 30$, $\dot{x}(0) = (0, 0, 1)^T$, $x(0) = (0, 0, 0)$, the rotation and translation needed to map the curve $\tilde{x}$ onto the geodesic $x$ is given by $h_0^{-1} = (m(x_0, T_0))^{-1}$. Note that $x(s) = R_0^T(\tilde{x}(s) - \tilde{x}_0)$, with $\tilde{x}_0 = (0, 0, -5)$ and $T_0 \in SO(3)$ given by Eq. (185). In this example both the curvature $\kappa$ and $z$ are always aligned with the $y$-axis which explains that the curve stays within the $yz$-plane.
