The Mathieu groups and their geometries

Hans Cuypers
Eindhoven University of Technology

1. Introduction

In the early 80-ties it became clear that the classification of the non-abelian finite simple groups was complete. Among the finite simple groups we find several families: the alternating groups and various families of groups of Lie-type and their twisted analogues. Besides these families there exist 26 sporadic finite simple groups.

Buildings are natural geometries for the groups of Lie-type (and, the thin building of type $A$ for the alternating groups). For the 26 sporadic groups there is no canonical type of geometry. The theory of diagram geometries, however, has opened various ways to associate geometries to these sporadic simple groups.

In these notes we consider five sporadic simple groups, the Mathieu groups $M_i$, $i \in \{11, 12, 22, 23, 24\}$, as well as some of their geometries. In particular, for the large Mathieu groups, i.e., $i \in \{22, 23, 24\}$, we will describe geometries with the following diagrams:

- $M_{22}$:
  \[
  \begin{array}{c}
    \bullet \\
    c \\
    \bullet
  \end{array}
  \]

- $M_{23}$:
  \[
  \begin{array}{c}
    \bullet \\
    c \\
    \bullet
  \end{array}
  \]

- $M_{24}$:
  \[
  \begin{array}{c}
    \bullet \\
    \bullet \\
    \bullet \\
    \bullet
  \end{array}
  \]

- $M_{22}$:
  \[
  \begin{array}{c}
    \bullet \\
    P \\
    \bullet
  \end{array}
  \]

- $M_{23}$:
  \[
  \begin{array}{c}
    \bullet \\
    P \\
    \bullet
  \end{array}
  \]

- $M_{24}$:
  \[
  \begin{array}{c}
    \bullet \\
    L
  \end{array}
  \]

The Mathieu groups were discovered by the French mathematician Émile Mathieu (1835–1890), who also discovered the large Mathieu groups $M_{22}$, $M_{23}$ and $M_{24}$. See [12, 13, 14]. They are remarkable groups: for example, apart from the symmetric and alternating groups, $M_{12}$ and $M_{24}$ are the only 5-transitive
The Mathieu groups and their geometries

permutation groups. After Mathieu’s discovery of these five sporadic simple
groups it took almost a century before the sixth sporadic simple group was
found.

Not only are the five Mathieu groups among the 26 sporadic simple groups,
they are also closely related to almost all the other sporadics. The geometries
we will describe in these notes are also closely connected to various geometries
associated to other sporadic simple groups. For example, they appear as residues
in the following geometries (see for example [6, 5]):

\[
\begin{align*}
HS &: \quad c \quad \cdots \quad c^* \\
F_{22} &: \quad c \\
F_{23} &: \quad \cdots \quad c \\
F_{24} &: \quad \cdots \quad c \\
McL &: \quad \cdots \quad P \\
M &: \quad L \quad \cdots \quad L^*
\end{align*}
\]

We note that the residue at the right most node of the last diagram is a
geometry for the the Conway group \(Co_1\).

2. Designs

A \(t-(v,k,\lambda)-\text{design}\) is a pair \((X,B)\) consisting of a set \(X\) of points and a set
\(B\) of subsets of \(X\) called blocks, such that

- \(|X| = v;\)
- \(|b| = k\) for all \(b \in B;\)
- any \(t\)-tuple of points is contained in exactly \(\lambda\) blocks.

See for example [10, 7].

**Example 2.1** A projective plane of order \(q\) is a \(2-(q^2 + q + 1, q + 1, 1)\)-design.
A unital of order \(q\) is a \(2-(q^3 + 1, q + 1, 1)\)-design. An affine plane of order \(q\)
is a \(2-(q^2, q, 1)\)-design.
Let \((X, B)\) be a \(t\)-design, and fix a point \(p\). The derived design at \(p\) is the \((t-1)\)-design \((X - \{p\}, \{b - \{p\} \mid b \in B, p \in b\})\). The design \((X, B)\) is called an extension of the design \(D\) if for all points \(p\) of \(X\) the derived design at \(p\) is isomorphic to \(D\).

**Proposition 2.2** If \((X, B)\) is an extension of a \(t-(v, k, \lambda)\) design with \(b\) blocks, then \(|B| = \frac{(v+1)b}{k+1}\) and hence \(k+1\) divides \((v+1)b\).

**Proof.** We count the number incident point-block pairs in 2 ways. Each point is on \(b\) blocks, so there are \((v+1)b\) such pairs. As each block contains \(k+1\) points, hence the number of incident point-block pairs equals \(|B|(k+1)\). Hence \(|B|(k+1) = (v+1)b\), and the Proposition follows. \(\square\)

A design is called an extension of a projective plane if its residual design is a projective plane. The extension of a projective plane of order \(q\) is a \(3-(q^2 + q + 2, q + 2, 1)\)-design. The set of points, the pairs of points and the set of blocks of an extension of a projective plane form rank 3 geometry with diagram

```
   c---c
```

Inductively, we can define a \(k\)-fold extension of a projective plane, where \(k \geq 2\), to be a design whose residual design is a \((k-1)\)-fold extension of a projective plane.

The points, pairs of points, ..., blocks, of a \(k\)-fold extension of a projective plane form a geometry with diagram

```
   c --- c
```

**Proposition 2.3** If \((X, B)\) is an extension of a projective plane of order \(q\), then \(q = 2, 4\) or \(10\).

**Proof.** The above Proposition implies that \(q+2\) divides \((q^2 + q + 2)(q^2 + q + 1)\). Hence \(q+2\) divides 12, and \(q = 2, 4\) or \(10\). \(\square\)

A few years ago, Lam and others did an extensive computer search for a plane of order 10. They did not find such a plane. Thus we are only concerned with \(q\) equal to 2 or 4.

The affine design on points and hyperplanes of \(AG(3, 2)\) is an extension of the Fano plane \(PG(2, 2)\). Indeed, if we take a 3-dimensional affine space over
The Mathieu groups and their geometries

$GF(2)$, then any 3 points are contained in a unique 2-dimensional subspace and the design is a $3 - (8, 4, 1)$-design.

We will study the extensions of a projective plane of order 4. Our main goal will be to prove (or at least give a sketch of the proof of) the following:

**Theorem 2.4** The projective plane $PG(2, 4)$ can be extended 3 times leading to the unique designs with parameters $3 - (22, 6, 1)$, $4 - (23, 7, 1)$ and $5 - (24, 8, 1)$.

### 3. The projective plane of order 4

Before proving Theorem 2.4 we first restrict attention to projective planes of order 4. The projective plane $PG(2, 4)$ is of course an example of such a plane. The following result implies that it is the unique example, see also [10, 7].

**Theorem 3.1** There is a unique projective plane of order 4.

**Proof.** Suppose $\Pi$ is a projective plane of order 4. Let $p_1$, $p_2$, $p_3$ and $p_4$ be 4 points in $\Pi$, no three being collinear. Let $L_{i,j}$ be the unique line through $p_i$ and $p_j$, where $i \neq j \in \{1, 2, 3, 4\}$. On these 6 lines we find $4 + 3 + 6 \cdot 2 = 19$ points of the plane.

Let $q_1$ be the intersection point of $L_{1,2}$ and $L_{3,4}$, $q_2$ the intersection point of $L_{1,3}$ and $L_{2,4}$ and $q_3$ the intersection point of $L_{2,3}$ and $L_{1,4}$. We claim that these points are collinear.

![Figure 1. The points $p_i$ and $q_j$](image)

Suppose not, then the line through $q_i$ and $q_j$, $i \neq j \in \{1, 2, 3\}$ contains a point of $\Pi$ not on the 6 lines $L_{n,m}$. This gives us 3 new points, and we have found $19 + 3 = 22 > 21$ points in $\Pi$. A contradiction. Thus $q_1$, $q_2$ and $q_3$ are
collinear. Let $M$ be the line through them and suppose $p_5$ and $p_6$ are the 2 remaining points of $M$.

In the set $O = \{p_1, \ldots, p_6\}$ no three points are collinear, and each line meets $O$ in 0 or 2 points. Moreover, this is the only set of 6 points containing $\{p_1, \ldots, p_4\}$ with this property. (Such a set is called a (hyper)oval in $\Pi$.)

We will encode the points and lines of $\Pi$ with the help of $O$.

Let $r$ be a point of $\Pi$ not in $O$, then there are three lines on $r$ meeting $O$ nontrivially. These lines determine a partition of $O$ into three pairs. We can identify the 15 points $r$ with the 15 partition of the 6 points of $O$ into three pairs.

The 15 lines of $\Pi$ meeting $O$ nontrivially can be identified with the pair of points of $O$ that they contain. It remains to identify the 6 lines missing $O$. They consist of 5 points that are all partitions of $O$ into 3 pairs. So each such line can be identified with a set of 5 pairwise disjoint partitions of $O$ in 3 pairs, which we call a factorisation of $O$. Incidences between points and lines can be read off from the encoding.

As there are exactly 6 such factorisations of $O$, see the lemma below, we have (up to isomorphism) a unique way to encode the points and lines of $\Pi$. This implies that $\Pi$ is the unique plane of order 4.

**Lemma 3.2** The set $\{1, \ldots, 6\}$ admits 6 factorisations, all equivalent under the action of $S_6$.

**Proof.** Suppose we have two partitions of $O = \{1, \ldots, 6\}$ into 3 pairs that are disjoint. Then these partitions correspond to the triples of disjoint edges in a hexagon with vertices 1 up to 6. A partition disjoint from these 2 corresponds to the 3 ‘long diagonals’ of the hexagon, or to one ‘long’ and two ‘short diagonals’. For a factorisation we can only take the three remaining partitions containing short diagonals.

Thus each factorisation is uniquely determined by any two of its partitions of $O$ into 3 pairs. This implies that there are $15 \cdot 8 / 5 \cdot 4 = 6$ factorisations of $O$, and clearly $S_6$ acts transitively on them. □
4. The automorphisms of the plane of order 4

The above proof of the uniqueness of the projective plane of order 4 gives us more information than only its uniqueness. It also shows that any set of 4 points, no 3 collinear, determines a unique hyperoval. Thus the plane contains $21 \cdot 20 \cdot 16 \cdot 9/6 \cdot 5 \cdot 4 \cdot 3 = 168$ hyperovals. Moreover, the automorphism group $Aut(\Pi)$ of $\Pi$ is transitive on these hyperovals, while the stabilizer of such a hyperoval is isomorphic to the group $S_6$. Hence $|Aut(\Pi)| = 168 \cdot |S_6|$.

Since $\Pi$ is isomorphic to $PG(2, 4)$, we know that (up to isomorphism) the group $PGL_3(4)$ is contained in the automorphism group of $\Pi$. This group has order 60480 and is of index 2 in $Aut(\Pi)$. The extra automorphism is induced by the field automorphism of order 2 of $GF(4)$. So the complete automorphism group of $\Pi$ is isomorphic to $P\Gamma L_3(4)$, the projective group of semi-linear transformations.

5. Hyperovals and Baer-subplanes in $PG(2, 4)$

The group $PSL_3(4)$ is normal in $P\Gamma L_3(4)$ and has index 6 in this group. It intersects the stabilizer of a hyperoval in a normal subgroup of $S_6$ of index at most 6. Hence this intersection is isomorphic to $A_6$. Thus $PSL_3(4)$ has 3 orbits of length 56 = 168/3 on the hyperovals. Since any hyperoval is uniquely determined by four of its points, two hyperovals can intersect in at most 3 points.

If we fix a hyperoval $O$, then an elation of $PG(2, 4)$ with center in the hyperoval fixes exactly two points of the hyperoval. All the other points are mapped outside of the hyperoval. In this way we obtain $15 \cdot 3 = 45$ hyperovals that are in the $PSL_3(4)$-orbit of $O$ and meet $O$ in 2 points. The remaining 10 hyperovals in the $PSL_3(4)$-orbit of $O$ have to be disjoint from $O$.

Thus we have found that two hyperovals are in the same $PSL_3(4)$-orbit if and only if they intersect in an even number of points.

In the above proof we not only encountered hyperovals, also the 7 points $p_1, \ldots, p_4, q_1, q_2$ and $q_3$ are of some interest. Together with the lines containing at least 2 of them they form a projective plane of order 2 called a Baer-subplane of $PG(2, 4)$.

As above, we can count the number of Baer-subplanes. There are 360 of them, forming one orbit under the group $P\Gamma L_3(4)$, but falling apart in 3 orbits of size 120 under the action of $PSL_3(4)$. Two Baer-subplanes are in the same $PSL_3(4)$-orbit if and only if they intersect in a line or a point.

The hyperoval $O = \{p_1, \ldots, p_6\}$ meets the Baer-subplane $S$ on the points $p_1, \ldots, p_4, q_1, q_2$ and $q_3$ in 4 points. Any other hyperoval in the $PSL_3(4)$-orbit of $O$ meets $S$ in 0, 2 or 4 points.

Summerizing we obtain the following. The projective plane of order 4 has the following properties:

- it has 168 (hyper)ovals, i.e., a set of 6 points no 3 collinear; the set $O$ of hyperovals falls apart into 3 $PSL_3(4)$-orbits $O_i$, with $i = 1, 2, 3$, of size 56.
- Two hyperovals are in the same $PSL_3(4)$-orbit if they intersect in an even number of points. Three noncollinear points are in a unique hyperoval of each $PSL_3(4)$-orbit.
The Mathieu groups and their geometries

- it has 360 Baer-subplanes, i.e., a set of 7 points meeting each line in 1 or 3 points; the set $S$ of Baer-subplanes falls apart into 3 $PSL_3(4)$-orbits $S_i$, with $i = 1, 2, 3$, of size 120.

Two hyperovals are in the same $PSL_3(4)$-orbit if and only if they intersect in an odd number of points. Any four noncollinear points are in a unique Baer-subplane.

- the indices $i$ and $j$ can be chosen in such a way that for $O \in O_i$, and $S \in S_j$, we have $|O \cap S|$ is even if and only if $i = j$.

6. The Mathieu-Witt designs

Let $(X, B) = PG(2, 4)$ be the projective plane of order 4, and let $\infty_1$, $\infty_2$, and $\infty_3$ be three new points. Construct the new structure $M_{24}$ with point set $X \cup \{\infty_1, \infty_2, \infty_3\}$ and with the following blocks:

- $L \cup \{\infty_1, \infty_2, \infty_3\}$, where $L \in B$;
- $O \cup \{\infty_1, \infty_2, \infty_3\} - \{\infty_i\}$ for each $O \in O_i$;
- $S \cup \{\infty_i\}$ for each $S \in S_i$;
- $L \Delta L'$ for all $L, L' \in B$, $L \neq L'$.

**Theorem 6.1** $M_{24}$ is a $5 - (24, 8, 1)$ design.

**Proof.** Observe that $M_{24}$ has 24 points and 759 blocks of size 8. So on average, every 5 tuple of points is in one block. Hence to prove that $M_{24}$ is a $5 - (24, 8, 1)$ design, it suffices to check that each 5-tuple of points is contained in at least one block.

Let $T$ be a 5-tuple of points.

If $\{\infty_1, \infty_2, \infty_3\} \subseteq T$, then the remaining two points of $T$ determine a unique line $L$ in $PG(2, 4)$. So the unique block containing $T$ is $\{\infty_1, \infty_2, \infty_3\} \cup L$.

Suppose $|\{\infty_1, \infty_2, \infty_3\} \cap T| = 2$ and let $\infty_i$ be not in $T$. If the three points of $T$ in $PG(2, q)$ are on a line $L$, then $T$ is contained in $\{\infty_1, \infty_2, \infty_3\} \cup L$. If the three points of $T$ inside $PG(2, 4)$ are not collinear then they determine a unique hyperoval $O$ in $O_i$. Again there is a unique block on $T$, namely $O \cup T$.

Now suppose $|\{\infty_1, \infty_2, \infty_3\} \cap T| = \infty_i$. If the remaining 4 points of $T$ are on a line $L$ of $PG(2, 4)$, then $\{\infty_1, \infty_2, \infty_3\} \cup L$ is a block on $T$. If no three of the four points are collinear, then these four points are in a unique hyperoval $O$ and a unique Baer-subplane $S$ of $PG(2, 4)$. If $S \in S_i$ then $S \cup \{\infty_i\}$ is a block on $T$. If $S \in S_j$, $j \neq i$, then $O$ is in $O_j$. Thus $T$ is contained in the block $O \cup \{\infty_1, \infty_2, \infty_3\} - \{\infty_j\}$.

Finally suppose that $T$ is contained in $PG(2, 4)$. If $T$ is contained in a hyperoval, then it is in some block. Hence we may assume that there are at least 3 points in $T$ on some line $L$ of $PG(2, 4)$. If $L$ meets $T$ in more than 3 points, then clearly $T$ is either contained in $L$ or in the symmetric difference of $L$ and another line of $PG(2, 4)$. Thus we can assume that $L \cap T$ contains just 3
points. Now let $L'$ be the line through the other two points of $T$. If $L' \cap L$ is a point of $T$, then $T$ is contained in a Baer-subplane. If $L' \cap L$ is not in $T$, the $T$ is contained in $L \Delta L'$. In both cases we have found a block on $T$. This finishes the proof that $\mathcal{M}_{24}$ is a $5 - (24, 8, 1)$ design. □

For $i = 1, 2, 3$, let $\mathcal{M}_{24-i}$ be the derived design of $\mathcal{M}_{25-i}$ at $\infty_i$. The designs $\mathcal{M}_i$, are called the Mathieu-Witt designs, as Witt was the first to study them, see [15, 11].

We prove uniqueness for the design $\mathcal{M}_{22}$:

**Proposition 6.2** There exists a unique $3 - (22, 6, 1)$ design.

**Proof.** Suppose $(X, B)$ is such a design. Fix a point $\infty$ in $X$. Then the residue at $\infty$ is a projective plane of order 4 and thus isomorphic to $PG(2, 4)$. Identify this residue with $PG(2, 4)$. As $|B| = 77$ we still have to identify the 56 blocks missing $\infty$. However, each such block is a set of 6 points in $PG(2, 4)$ meeting each line of $PG(2, 4)$ in 0 or 2 points, so it is a hyperoval. As 2 blocks meet in 0 or 2 points, the blocks in $B$ missing $\infty$ are all in one $PSL_3(4)$ orbit on the 168 hyperovals of $PG(2, 4)$. In fact they form the complete set of 56 hyperovals in one such orbit. In particular $(X, B)$ is isomorphic to $\mathcal{M}_{22}$. □

Similarly one can check that the designs $\mathcal{M}_{23}$ and $\mathcal{M}_{24}$ are the unique designs with the parameters $4 - (23, 7, 1)$, respectively, $5 - (24, 8, 1)$.

**Theorem 6.3** There exists a unique $4 - (23, 7, 1)$-design and a unique $5 - (24, 8, 1)$-design.

Now 6.2 and 6.3 prove Theorem 2.4.

7. The large Mathieu groups

The group Aut$(\mathcal{M}_{24})$ is the Mathieu group $M_{24}$. Inductively we define the stabilizer of $\infty_1$ in $M_{25-i}$ to be the group $M_{24-i}$. By the above construction and uniqueness proofs it is clear that $M_{24}$ is 3-transitive on the points of $\mathcal{M}_{24}$ (the choise and order of the points in $\{\infty_1, \infty_2, \infty_3\}$ is of no importance in the above). Moreover, $M_{21}$, the pointwise stabilizer of $\{\infty_1, \infty_2, \infty_3\}$ is isomorphic to the simple group $PSL_3(4)$, which is 2-transitive on the remaining 21 points. Hence we obtain:

**Theorem 7.1** The group $M_{24}$ is 5-transitive on the 24 points of $\mathcal{M}_{24}$.

Its order is 24.23.22.21.20.16.3.

The group $M_{24-i}$, $i = 1, 2, 3$, is $(5 - i)$-transitive on 24 – $i$ points of $\mathcal{M}_{24-i}$.

In the remainder of this section we prove simplicity of the large Mathieu groups (see also [3, 2]):

**Theorem 7.2** The groups $M_{22}$, $M_{23}$ and $M_{24}$ are simple.
A permutation group $G$ acting on a set $\Omega$ is said to act \textit{primitively}, if there exists no non-trivial $G$-invariant partition of the set $\Omega$. We say that $G$ acts \textit{regularly} on $\Omega$, if $G$ is transitive on $\Omega$ and the stabilizer in $G$ of an element of $\Omega$ is the trivial group. (See [1, 3].)

**Proposition 7.3** If $G$ acts primitively on $\Omega$ and $N \neq 1$ is a normal subgroup of $G$, then $N$ is transitive on $\Omega$.

**Proof.** Suppose $N$ is not transitive on $\Omega$, and let $\Omega_1, \ldots, \Omega_r$ be the orbits of $N$ on $\Omega$. We claim that $\Omega_1 \cup \ldots \cup \Omega_r$ is a $G$-invariant partition of $\Omega$.

Let $g \in G$ and suppose $g(\Omega_i)$ intersects $\Omega_j$ nontrivially and the intersection contains an element $g(\omega)$. Then, since $Ng = gN$ we have $g(\Omega_i) = \{gn(\omega) \mid n \in N\} = \{ng(\omega) \mid n \in N\}$, is the $N$-orbit of $g(\omega)$, and thus equal to $\Omega_j$. Thus indeed we have found a $G$-invariant partition of $\Omega$ contradicting the primitivity. \square

**Proposition 7.4** Suppose $G$ acts primitively on a set $\Omega$ and the point stabilizer $G_\omega$ is simple for some $\omega \in \Omega$. Then either $G$ is simple or $G$ contains a normal subgroup $N$ which acts regularly on $\Omega$.

**Proof.** Let $N$ be a nontrivial normal subgroup of $G$. By the above result $N$ is transitive. But $N \cap G_\omega \leq G_\omega$ and thus either $G_\omega$ or trivial.

If this intersection is trivial, $N$ acts regularly, otherwise $N$ contains the maximal subgroup $G_\omega$ as a proper subgroup and thus equals $G$. Hence either $G$ is simple or contains a regular normal subgroup. \square

Suppose $G$ acts transitively on $\Omega$, and $G_\omega$ is the stabilizer of some point $\omega$ of $\Omega$. We can identify the action of $G$ on $\Omega$ with the action of $G$ on $G/G_\omega$, where the action of $g \in G$ is defined by $g : hG_\omega \mapsto ghG_\omega$ for all $h \in G$.

If $N$ is a regular normal subgroup of $G$ on $\Omega$, there is a unique element in $N \cap hG_\omega$ for each $h \in G$. Thus we can identify $hG_\omega$ with this unique element in the intersection. Since for $g \in G_\omega$ we have $gnG_\omega = gng^{-1}G_\omega$, the action of $g \in G_\omega$ is defined by $g : n \mapsto gng^{-1}$.

If $G$ is 2-transitive and has a regular normal subgroup $N$, then all non-identity elements of $N$ are conjugate. Thus they all have the same order $p$, for some prime $p$, and it is straightforward to check that $N \simeq Z_p^n$ for some $n$.

**Exercise 7.5** Let $G$ be a $t$-transitive group on a set $\Omega$ with regular normal subgroup $N$. Show that:

(a) if $t = 3$, then $N \simeq Z_2^n$ or $G \simeq S_3$;

(b) if $t \geq 4$, then $t = 4$, $N \simeq Z_2^2$ and $G \simeq S_4$.

Thus we have:
The Mathieu groups and their geometries

Theorem 7.6 Suppose $G$ acts 2-transitively on $\Omega$ and $N$ is a regular normal subgroup of $G$. Then $N \cong Z_p^n$ for some prime $p$. In particular, $|\Omega| = p^n$.

Moreover, if $G$ is 3-transitive, then $p = 2$ or $G \cong S_3$, and if $t \geq 4$, then $G \cong S_4$ in its natural action on 4 elements.

We can now finish the proof of Theorem 7.2 for the large Mathieu groups. As $M_{22}$ is 3-transitive, $M_{21} \cong PSL_3(4)$ is simple, and 22 is not a prime power, the above results imply that $M_{22}$ is simple.

Since $M_{23}$ is 4-transitive and $M_{22}$ is simple, we also find that $M_{23}$ is simple. Similarly we obtain that $M_{24}$ is simple.

8. Some related geometries for the large Mathieu groups

In this section we describe some interesting geometries related to the Mathieu-Witt designs. They can be found in for example [5, 6, 4].

8.1 The near hexagon related to $M_{24}$ Consider the large Mathieu-Witt design $M_{24}$. This design contains 759 blocks. If $b_1$ and $b_2$ are two disjoint blocks, then it easily checked that the complement of $b_1 \cup b_2$ is also a block. We can use this to define a partial linear space $N$ on the blocks of $M_{24}$: The lines of this partial linear space are the triples of pairwise disjoint blocks. This partial linear space $N$ is called the near hexagon related to $M_{24}$.

Exercise 8.2 Check that this near hexagon satisfies the following (see [4]):

(a) The distance between two blocks $b$ and $b'$ in the collinearity graph of the near hexagon is equal to 2, if the two blocks meet in 4 points and 3, if they meet in 2 points.

(b) Given a line $l$ and a block $b$, then there is a unique block on $l$ closest to $b$.

(c) The collinearity graph is distance regular.

8.3 Consider a subset $S_1$ of 4 points of $M_{24}$. For each point $x \notin S_1$, there is a unique block containing $S_1 \cup \{x\}$. Hence there are exactly 5 blocks $b_i$, $2 = 1, \ldots, 6$ containing $S_1$. Let $S_i$ be the complement of $S$ in $b_i$. Then the $\bigcup_{i \in \{1, \ldots, 6\}} S_i$ is a partition of the 24 points of $M_{24}$. The union of any two elements from this partition is a block. There are 15 such blocks. These 15 blocks are the points of a subgeometry of $N$, called a quad, which is a generalized quadrangle of order $(2,2)$. (Check this!)

The geometry of blocks, lines (triples of disjoint blocks) and quads has Buekenhout diagram

\[ L \]
The Mathieu groups and their geometries

To see this we have to check that the lines and quads on a fixed block form a linear space.

Fix a block $b$ and two lines on $b$, say $\{b, b_1, b_2\}$ and $\{b, b'_1, b'_2\}$. Then $b'_i \cap b'_j$ contains 4 points. Hence there is a unique quad containing the two lines. This easily implies that the residue at a block is a linear space of order 2. It contains 15 lines and 35 quads. Actually $L$ is isomorphic to the linear space of points and lines of $PG(3, 2)$.

Exercise 8.4 Prove that the residue of a block is indeed the point-line space of $PG(3, 2)$.

8.5 Two Petersen geometries. Let $\mathcal{N}$ be the geometry of blocks, lines and quads of the near hexagon constructed in the previous section. Fix a point $p$ of the design $M_{24}$. Then the set $\mathcal{H}_p$ consisting of all blocks of $M_{24}$ containing $p$ is a geometric hyperplane of the near hexagon $\mathcal{N}$. Indeed, as any line of the near hexagon consists of a partition of the point set of $M_{24}$ into 3 blocks, every line of $\mathcal{N}$ has a unique block in $\mathcal{H}_p$.

We can now construct a rank 4 geometry as follows: The type 1 elements are all the blocks not in $\mathcal{H}_p$. Type 2 are pairwise disjoint blocks not containing $p$. The elements of type 3 are the complements in quads from $\mathcal{H}_p$. Notice that such complements are Petersen graphs. And finally, the type 4 elements are the 23 points different from $p$. Incidence between the elements of type 1, 2 and 3 is inherited from the near hexagon geometry $\mathcal{N}$. A point $q \neq p$ is incident with block, pair of disjoint blocks or Petersen graph, if and only if it is not contained in the block or blocks involved in the disjoint pair or Petersen graph.

The resulting geometry has diagram

```
    P
```

Its automorphism group contains of course (and is actually equal to) $M_{23}$. The geometry is called the Petersen geometry for $M_{23}$. The residue of a point is the Petersen geometry for $M_{22}$ with diagram

```
P
```

Exercise 8.6 Determine the number of elements of each type in both Petersen geometries described above.

We notice that there are also Petersen geometries related to the sporadic groups $Co_2$, $J_4$ and the Baby Monster $BM$, see [6].
9. The small Mathieu groups

In this section we sketch the construction of the small Mathieu groups and their designs. Following [11], see also [9], we start with a 2-(9,3,1) design and will extend it 3 times to obtain a 5-(12,6,1)-design. The automorphism group of this design contains the 5-transitive group $M_{12}$. The one and two point stabilizers in this group are the groups $M_{11}$ and $M_{10}$, respectively. These groups are the so called small Mathieu groups. The groups $M_{11}$ and $M_{12}$ are among the 26 sporadic simple groups. The group $M_{10}$ contains a normal subgroup of index 2 isomorphic to the alternating group $A_6$.

The designs we construct carry the structure of diagram geometries with diagram

$$M_{10} : \quad \text{Af}$$

$$M_{11} : \quad c \quad \text{Af}$$

$$M_{12} : \quad c \quad \text{Af}$$

9.1 The affine plane of order 3. An example of a 2-(9,3,1) design is the affine plane of order 3: as points we take the vectors of the vector space $GF(3)^2$, where $GF(3)$ denotes the field with 3 elements. The blocks (also called lines) are the triples of points contained in a coset of a 1-dimensional subspace. Indeed, there are 9 points in the design; any block consists of 3 points and any pair of points is in a unique coset of a 1-dimensional subspace.

It is not hard to show that this is, up to isomorphism, the only 2-(9,3,1) design. For this reason, the design is also called the affine plane of order 3.

Let us denote this unique design by $\Theta$. It is displayed in Figure 3. Its points and lines are encoded as follows:

<table>
<thead>
<tr>
<th>points</th>
<th>lines</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0,0)</td>
<td>1 2 3 1 6 8</td>
</tr>
<tr>
<td>(1,0)</td>
<td>1 5 9 1 4 7</td>
</tr>
<tr>
<td>(-1,0)</td>
<td>2 6 7 2 4 9</td>
</tr>
<tr>
<td>(0,1)</td>
<td>2 5 8 3 4 8</td>
</tr>
<tr>
<td>(1,1)</td>
<td>3 5 7 3 6 9</td>
</tr>
<tr>
<td>(-1,1)</td>
<td>4 5 6 7 8 9</td>
</tr>
<tr>
<td>(0,-1)</td>
<td></td>
</tr>
<tr>
<td>(1,-1)</td>
<td></td>
</tr>
<tr>
<td>(-1,-1)</td>
<td></td>
</tr>
</tbody>
</table>

Of course, the automorphism group of the design contains the group of translations, a group of order 9. The stabilizer of (0,0) contains the group $GL_2(3)$. In particular, the automorphism group of the design contains a group isomorphic to the split extension $3^2:GL_2(3)$. The order of this group is $3^2 \cdot 48 = 432$. 

12
As indicated above, we will consider the automorphism group of $\Theta$ as a subgroup of the permutation group on the set $P$ of points. With the labeling given in Figure 3 this means it is a subgroup of $S_9$.

An easy check shows that the following permutations are contained in $H := \text{Aut}(\Theta)$:

$$a = (1, 2, 3)(4, 5, 6)(7, 8, 9), \quad \text{a translation}$$
$$b = (1, 4, 7)(2, 5, 8)(3, 6, 9), \quad \text{a translation}$$
$$c = (2, 9, 3, 5)(4, 6, 7, 8),$$
$$d = (2, 7, 3, 4)(5, 8, 9, 6),$$
$$e = (5, 7)(4, 9)(6, 8),$$
$$f = (4, 7)(5, 8)(6, 9).$$

The subgroup $G := \langle a, b, c, d \rangle$ of $H$ is also 2-transitive on the points of $\Theta$. It is a normal subgroup of $H$ of order 72.

9.2 Extensions of the affine plane and the group $M_{10}$. Suppose $\Delta = (P, B)$ is a 3-(10, 4, 1) design. Then the number of blocks in $B$ equals $10 \cdot 9 \cdot 8 / (4 \cdot 3 \cdot 2) = 30$. Moreover, each point is on 12 blocks. Fix some point $p$ of $\Delta$, and consider the residue $\Delta_p$ of $\Delta$ at the point $p$. Then $\Delta_p$ is a 2-(9, 3, 1) design, and hence isomorphic to the affine plane $\Theta$ discussed above. To be specific, take $p = 10$ and identify $\Delta_{10}$ with this affine plane. The 12 blocks of $\Delta$ on $p = 10$ are then the sets $\{10\} \cup b$ where $b$ is a block of $\Theta$.

Next we want to show how to reconstruct $\Delta$ from the design $\Theta$. For that purpose we still have to determine the remaining $30 - 12 = 18$ blocks. A block of $\Delta$ not containing 10 consists of 4 points of $\Theta$ meeting any block of $\Theta$ in at most 2 points. Any set of 4 points of $\Theta$ with this property is called a 4-arc. The number of 4-arcs in $\Theta$ is equal to $54 = 9 \cdot 8 \cdot 6 \cdot 3 / (4 \cdot 3 \cdot 2 \cdot 1)$.

We can easily check that $H$ is transitive on the set of 4-arcs of $\Theta$. However, under the action of the smaller group $G$ this orbit splits into 3 orbits of size 18.

Exercise 9.3 Prove that two 4-arcs are in the same $G$-orbit if and only if they intersect in an even number of points.
Figure 4. The affine plane $\Delta_1$.

Let $\Delta$ be the following design: the point set is $\{1, \ldots, 10\}$; the blocks of $\Delta$ are the 12 sets $\{10\} \cup b$, where $b$ is a block of $\Theta$, and the eighteen 4-arcs in the $G$-orbit of $\{1, 2, 4, 5\}$. We check that $\Delta$ is a 3-(10, 4, 1) design.

Fix the point 1 and consider the residue $\Delta_1$. The 9 points and 12 blocks form a 2-(9, 3, 1) design isomorphic to $\Theta$, see Figure 4. The automorphism group of $\Delta_1$ contains the translation $g = (10, 2, 3)(4, 9, 8)(7, 6, 5)$.

It is easily checked that the block set of $\Delta$ is invariant under $g$, so $g \in \text{Aut}(\Delta)$.

Let $M_{10}$ be the subgroup of $S_{10}$ generated by $G$ and the element $g$. Then $M_{10}$ is transitive on the 10 points of $\Delta$. Hence at each point $p$ of $\Delta$ the residual design is an affine plane. But then $\Delta$ itself is indeed a 3-(10, 4, 1) design. An order computation yields that $|M_{10}| = 10 \cdot 9 \cdot 8 = 720$: The point stabilizer of 10 equals $G$. As $G$ is 2-transitive on $\{1, \ldots, 9\}$, the group $M_{10}$ is 3-transitive on $\{1, \ldots, 10\}$; in particular, it is transitive on the 30 blocks. It is called the Mathieu group of degree 10.

Exercise 9.4 Prove the uniqueness of a 3-(10, 4, 1)-design.

9.5 Multiple extensions and the small Mathieu groups. The preceding procedure gives us three ways, corresponding to the three choices for the $G$-orbit on the 4-arcs of $\Theta$, to complete the design $\Theta$ to a 3-(10, 4, 1) design $\Delta$. As stated above all three ways lead to isomorphic designs; here it follows directly from the fact that $H$ normalizes $G$ and permutes the 3 choices of 18 blocks. However, it also shows how we may proceed to extend $\Delta$ to a 4-(11, 5, 1) design and even to a 5-(12, 6, 1) design. We will construct a 4-(11, 5, 1) design and a 5-(12, 6, 1) design with the help of a 4- and a 5-transitive group.

Let $O_{10} = \{1, 2, 4, 5\}^G$, $O_{11} = \{1, 2, 4, 8\}^G$ and $O_{12} = \{1, 2, 4, 6\}^G$ be the three orbits of $G$ on the 4-arcs of $\Theta$. For $i = 10, 11, 12$, extend $\Theta$ to a design $\Delta_i$ with point set $\{1, \ldots, 9\} \cup \{i\}$, and with blocks the sets $b \cup \{i\}$ (where $b$ runs through the blocks of $\Theta$) and the sets in $O_i$. Then both $\Delta^{11}$ and $\Delta^{12}$ are 3-(10, 4, 1) designs just as $\Delta^{10} = \Delta$. 

14
As before we can prove that

\[ g_2 = (11, 2, 3)(4, 6, 9)(7, 5, 8) \]

and

\[ g_3 = (12, 2, 3)(4, 8, 5)(7, 9, 6) \]

are automorphisms of \( \Delta^{11} \) and \( \Delta^{12} \), respectively.

Consider the groups \( M_{11} = \langle M_{10}, g_2 \rangle \) and \( M_{12} = \langle M_{11}, g_3 \rangle \). Since \( g_2 \) moves 11 and \( g_3 \) moves 12, these groups are transitive on \( \{1, \ldots, 11\} \) and \( \{1, \ldots, 12\} \), respectively. Actually, as \( M_{10} \) is 3-transitive, we find that \( M_{11} \) is at least 4-transitive and \( M_{12} \) at least 5-transitive.

Now consider a design \( M_{12} \) on the 12 points \( \{1, \ldots, 12\} \) with the following 132 blocks:

- \( \{10, 11, 12\} \cup L \), where \( L \) is a line of \( \Theta \).
- \( \{10, 11, 12\} \cup O \setminus \{i\} \), where \( O \in O_i \), with \( i \in \{10, 11, 12\} \).
- \( \{i\} \cup L \cup M \), where \( L, M \) are intersecting lines of \( \Theta \) and \( L \Delta M \) is a 4-arc in \( O_i \), again \( i \in \{10, 11, 12\} \).
- \( L \cup M \), where \( L, M \) are distinct parallel lines of \( \Theta \).

(Notice that the designs \( \Delta^i \) appear as residues of two points.) An easy check shows that \( M_{12} \) is contained in the automorphism group of this design. As \( M_{12} \) is 5-transitive on the points, we find that any 5-tuple is contained in at least one block. But then it is contained in exactly one block. This implies that \( M_{12} \) is a 5-(12, 6, 1) design.

Order calculations reveal that

\[ |M_{11}| = 11 \cdot |M_{10}| = 11 \cdot 10 \cdot 9 \cdot 8 = 7920, \]

and

\[ |M_{12}| = 12 \cdot |M_{11}| = 12 \cdot 11 \cdot 10 \cdot 9 \cdot 8 = 95040. \]

The groups \( M_{11} \) and \( M_{12} \) are called the Mathieu groups of degrees 11 and 12, respectively.

**Exercise 9.6** Prove that \( M_{11} \) and \( M_{12} \) are simple. (Here you may use the fact that \( M_{10} \simeq A_6 \cdot 2 \).)
