**Jonas Kahn**, Université de Lille 1, France, [jonas.kahn@math.univ-lille1.fr](mailto:jonas.kahn@math.univ-lille1.fr)

We introduce a new partial order on the class of stochastically monotone Markov kernels having a given stationary distribution  $\pi$  on a given finite partially ordered state space  $\mathcal{X}$ . When  $K \preceq L$  in this partial order we say that  $K$  and  $L$  satisfy a *comparison inequality*. We establish that if  $K_1, \dots, K_t$  and  $L_1, \dots, L_t$  are reversible and  $K_s \preceq L_s$  for  $s = 1, \dots, t$ , then  $K_1 \cdots K_t \preceq L_1 \cdots L_t$ . In particular, in the time-homogeneous case we have  $K^t \preceq L^t$  for every  $t$  if  $K$  and  $L$  are reversible and  $K \preceq L$ , and using this we show that (for suitable common initial distributions) the Markov chain  $Y$  with kernel  $K$  mixes faster than the chain  $Z$  with kernel  $L$ , in the strong sense that *at every time  $t$*  the discrepancy—measured by total variation distance or separation or  $L^2$ -distance—between the law of  $Y_t$  and  $\pi$  is smaller than that between the law of  $Z_t$  and  $\pi$ .

Using comparison inequalities together with specialized arguments to remove the stochastic monotonicity restriction, we answer a question of Persi Diaconis by showing that, among all symmetric birth-and-death kernels on the path  $\mathcal{X} = \{0, \dots, n\}$ , the one (we call it the *uniform chain*) that produces fastest convergence from initial state 0 to the uniform distribution has transition probability 1/2 in each direction along each edge of the path, with holding probability 1/2 at each endpoint.

We also use comparison inequalities

- (i) to identify, when  $\pi$  is a given log-concave distribution on the path, the fastest-mixing stochastically monotone birth-and-death chain started at 0, and
- (ii) to recover and extend a result of Peres and Winkler that extra updates do not delay mixing for monotone spin systems.

Among the fastest-mixing chains in (i), we show that the chain for uniform  $\pi$  is slowest in the sense of maximizing separation at every time.
