Reduction rules for reset/inhibitor nets

H.M.W. Verbeek, M.T. Wynn, W.M.P. van der Aalst, A.H.M. ter Hofstede

Abstract

Reset/inhibitor nets are Petri nets extended with reset arcs and inhibitor arcs. These extensions can be used to model cancellation and blocking. A reset arc allows a transition to remove all tokens from a certain place when the transition fires. An inhibitor arc can stop a transition from being enabled if the place contains one or more tokens. While reset/inhibitor nets increase the expressive power of Petri nets, they also result in increased complexity of analysis techniques. One way of speeding up Petri net analysis is to apply reduction rules. Unfortunately, many of the rules defined for classical Petri nets do not hold in the presence of reset and/or inhibitor arcs. Moreover, new rules can be added. This is the first paper systematically presenting a comprehensive set of reduction rules for reset/inhibitor nets. These rules are liveness and boundedness preserving and are able to dramatically reduce models and their state spaces. It can be observed that most of the modeling languages used in practice have features related to cancellation and blocking. Therefore, this work is highly relevant for all kinds of application areas where analysis is currently intractable.

1. Introduction

Petri nets are a well-established formalism for modeling and analyzing concurrent systems. Over time many extensions have been proposed in order to capture specific, possibly quite complex, behavior in a more direct manner. These extensions include reset arcs and inhibitor arcs. Reset arcs provide a natural means of dealing with cancellation behavior. A reset arc is a type of arc that goes from a place to a transition and its semantics is to remove all tokens from that place when the transition fires [1–5]. For example, a customer may cancel a travel request which would result in certain activities terminating. Inhibitor arcs provide a natural means of dealing with blocking behavior. An inhibitor arc is a type of arc that goes from a place to a transition and its semantics is to prevent the transition from firing when the place contains one or more tokens [6,7]. For example, an invoice should only be generated when the items ordered are ready for delivery and the order has not been canceled.

While these extensions increase the expressiveness of Petri nets, they can compromise analysis techniques and certain properties may even become undecidable. Examples of such properties are

- the reachability problem, which is undecidable for Petri nets with inhibitor arcs and for Petri nets with reset arcs, and
- the existence of place invariants, which do not hold for Petri nets with reset arcs.

Examples of such analysis techniques are reachability and coverability analysis, which can be used to detect structural and behavioral properties of Petri nets \[8\]. Coverability analysis has been extended in order to deal with Petri nets with reset arcs \[4\] and also in order to deal with Petri nets with inhibitor arcs \[9\]. Limiting the practical applicability of reachability and coverability analysis is the problem of state explosion, which occurs in nets where a very large number of markings need to be considered for analysis.

Reduction rules for Petri nets have been proposed to deal with the state explosion problem. Reduction rules can reduce the size of the net while preserving certain essential properties such as liveness. Their application therefore has the potential to significantly speed up the analysis process. A significant body of research exists that addresses the concept of reduction in the area of Petri nets (see e.g. \[10,8\]) and its various subclasses (see e.g. \[11\]) and extensions (see e.g. \[12\]). However, as far as we know, the issue of reduction in Petri nets with both reset and inhibitor arcs has not been considered in the literature. Existing reduction rules are not directly applicable in the presence of both types of arcs.

Business process modeling languages used in practice, e.g. UML Activity Diagrams \[13\], the Business Process Modeling Notation (BPMN) \[14\] and the Business Process Execution Language (BPEL) \[15\], offer features which correspond to cancellation and blocking. To capture their semantics, reset arcs and inhibitors arcs can model cancellation and blocking. Hence the analysis of business process modeling languages mapped to Petri nets with reset and inhibitor arcs could benefit from reduction rules developed for such nets. Here it can be added that the application of general translations of modeling notations to Petri nets typically results in nets with many “dummy” transitions (with a single input place and a single output place) that are used to simply glue various parts of the model together. Reduction rules can then be quite effective in reducing the resulting nets, as these rules are likely to reduce these “dummy” transitions.

In this paper a number of reduction rules for Petri nets with reset and inhibitor arcs are proposed. These are inspired by reduction rules provided for Petri nets in \[10,8\] and for Free Choice Petri nets provided in \[11\]. Additional conditions are proposed to cater for the presence of reset and inhibitor arcs. The proposed rules are shown to preserve liveness and boundedness.

The contributions of the paper are as follows. (1) The paper aims to make a contribution to the body of theory in Petri nets with reset and inhibitor arcs by providing a set of liveness and boundedness preserving reduction rules. (2) In practical terms, the reduction rules presented in this paper can be used for an efficient analysis of business process models described using various business process modeling languages that support cancellation and blocking such as the Business Process Modeling Notation (BPMN), the Business Process Execution Language (BPEL) and the Unified Modeling Language (UML).

The organization of the remainder of this paper is as follows. Section 2 provides terminology, concepts, notations and formal definitions that are required in subsequent sections of the paper. In Section 3 a set of liveness and boundedness preserving reduction rules for Petri nets with reset and inhibitor arcs are introduced. Section 4 discusses related work and Section 5 concludes the paper.

2. Preliminaries

This section provides the formal foundation for Petri nets and reset/inhibitor nets as it is used throughout this paper. Readers familiar with Petri nets, reset arcs, and inhibitor arcs, may skip this section, although the particular notations used in the paper might still be of interest to them.

2.1. Petri nets

In its basic form, a Petri net consists of a set of places, a set of transitions, and a set of arcs that connect places to transitions and vice versa. Note that arcs do not connect places to places or transitions to transitions.

Definition 1 (Petri net). (See \[8\].) A Petri net is a tuple \((P, T, F)\) where \(P\) is a finite set of places, \(T\) is a finite set of transitions, \(P \cap T = \emptyset\) and \(F \subseteq (P \times T) \cup (T \times P)\) is the (finite) set of arcs.

Let \(N\) be a Petri net \((P, T, F)\), and let \(x\) be a node of \(N\), that is, \(x \in P \cup T\). We use \(\bullet x\) and \(x\bullet\) to denote the set of input nodes and output nodes respectively. If the net involved cannot be understood from the context, we explicitly include net \(N\) in the notation and we write \(N \bullet x\) and \(x N\bullet\). Relation \(F\) is a function and \(F(x, y)\) evaluates to 1 if \((x, y) \in F\) and to 0 otherwise.

To every place of a Petri net \(N = (P, T, F)\) a (non-negative) counter can be associated. The actual values of all these counters of all places of the net is called a marking \(M\) of that net, and corresponds to a state of the net: \(M \in P \mapsto N\). Note that \(M\) can also be interpreted as a vector, function, or multiset over the set of places \(P\). We use \(M(N)\) to denote the set of all possible markings of a net \(N\). Typically, a marking \(M \in M(N)\) is visualized by putting \(M(p)\) tokens (black dots) into every place \(p\). Thus, the number of tokens in a place corresponds to the actual value of its counter.

A marking \(M\) contains another marking \(M'\), denoted \(M \geq M'\), iff for every \(p \in P\): \(M(p) \geq M'(p)\). Likewise, a marking \(M\) exceeds a marking \(M'\), denoted \(M > M'\), iff \(M > M'\) and \(M \neq M'\). Markings \(M\) and \(M'\) can be added, denoted \(M + M'\), in a straightforward way (for every \(p \in P\): \((M + M')(p) = M(p) + M'(p)\)). Furthermore, these markings can be subtracted,
denoted $M \rightarrow M'$, in a straightforward way (for every $p \in P$: $(M - M')(p) = M(p) - M'(p)$), provided that the former marking contains the latter ($M \geq M'$). In definitions to come, we use the fact that a set of places induces a marking in a straightforward way (by associating the value 1 to every place). As a result, we can add (subtract) a set of places to (from) a marking, and can compare sets of places to markings. Finally, we use $0$ to denote the empty marking, that is, $0(p) = 0$ for every place $p$.

Whereas places hold the current state of a Petri net, transitions may change this current state by firing. However, before a transition fires, it should be enabled. A transition is enabled if all input places contain tokens, that is, if all the counters of its input places exceed zero. If an enabled transition fires, it removes a token from every input place and adds a token to every output place, that is, it decreases the counter of its input places, and increments the counter of its output places. Note that because the transition is enabled, the counters of its input places will be at least 0 after the transition has fired.

**Definition 2** (Enabling and firing a transition in a Petri net). Let $N = (P, T, F)$ be a Petri net, $t \in T$ and $M, M' \in \mathbb{M}(N)$. Transition $t$ is enabled at $M$, denoted as $M[t]$, iff $M \geq \bullet t$. If transition $t$ is enabled at $M$, then it may fire, which results in a marking $M'$, where $M' = M - \bullet t + \bullet t$. This, we denote by $M \xrightarrow{N,t} M'$.

If there can be no confusion regarding the net, the expression is abbreviated as $M \xrightarrow{t} M'$ and if the transition is not relevant, it is written as $M \rightarrow M'$. We write $M = M_{\sigma} \rightarrow M_{\sigma}$ if $\sigma = t_1t_2 \ldots t_n$ is an occurrence sequence leading from $M$ to $M_n$ i.e. $M \xrightarrow{N.t_1} M_1 \xrightarrow{N.t_2} \ldots \xrightarrow{N.t_n} M_n$. The empty occurrence sequence is denoted $\epsilon$.

A Petri net $N = (P, T, F)$ together with a marking $M \in \mathbb{M}(P)$ is called a marked Petri net, denoted $(N, M)$. Clearly, a marked Petri net induces a state space, where every state corresponds to a reachable marking. The set of all reachable markings is called the reachability set of the marked Petri net $(N, M)$ and is denoted $N[M]$. This reachability set is the minimal set that satisfies the following conditions:

- the initial marking is reachable, that is, $M \in N[M]$, and
- if a reachable marking enables some transition, then the marking that results from firing this transition is also reachable, that is, if $M' \in N[M]$ and $M'[t]$ then $(M' - \bullet t + \bullet t) \in N[M]$.

Note that we restrict ourselves to single-step semantics in this paper, that is, any transition fires in isolation. In contrast, in a multi-step semantics, many transitions may fire together, which could lead to additional reachable states. The reason for restricting ourselves to single-step semantics is that we assume that the corresponding process model is meant be executed on some process server which will satisfy at least the well-known ACID (Atomicity, Consistency, Isolation, Durability) property. As a result, every transition in the Petri net can be isolated from the others.

A marked Petri net $(N, M)$ is called live iff every transition can get enabled from every reachable marking.

**Definition 3** (Liveness). (See [11].) Let $(N, M)$ be a marked Petri net with the initial marking $M$. $(N, M)$ is live iff for every $M' \in N[M]$ and every $t \in T$ there exists an $M'' \in N[M']$ such that $M''[t]$.

A marked Petri net $(N, M)$ is called bounded iff every counter of every place has a maximal value. As a result, for a bounded marked Petri net, the number of reachable states is finite.

**Definition 4** (Boundedness). (See [11].) Let $(N, M)$ be a marked Petri net with the initial marking $M$. $(N, M)$ is bounded iff there exists a natural number $b \in \mathbb{N}$ such that for every $M' \in N[M]$ and $p \in P$ it holds that $M'(p) \leq b$.

2.2. Reset/inhibitor nets

A reset net [2] is a Petri net with special reset arcs, that can clear the tokens in selected places. Reset arcs are represented as doubled-headed arrows. An inhibitor net [6,9] is a Petri net with inhibitor arcs. Inhibitor arcs are used to test for absence of tokens in a place. A transition can only fire if all its inhibitor places are empty. Graphically, an inhibitor arc connects a place to a transition and the arc ends with an empty circle on the transition side.

**Definition 5** (Reset/inhibitor net). A reset/inhibitor net is a tuple $(P, T, F, R, I)$ where $(P, T, F)$ is a Petri net, $R : T \rightarrow \mathbb{P}(P)$ ($\mathbb{P}(P)$ denotes the powerset of $P$) provides the reset places for the transitions, and $I : T \rightarrow \mathbb{P}(P)$ specifies the set of inhibitor places for each transition.

The notations $R(t)$ and $I(t)$ for a transition $t$ return the (possibly empty) set of places that it resets and that inhibit it. We also write $R^-(p)$ and $I^-(p)$ for a place $p$, which returns the set of transitions that can reset $p$ and that are inhibited by $p$. Furthermore, we introduce a notation to project a marking $M$ onto a set of places $P$, denoted $M | P : (M | P)(p) = M(p)$ if $p \in P$ and $(M | P)(p) = 0$ otherwise.

The notions of inputs, outputs and markings defined for an ordinary Petri net also apply to reset/inhibitor nets. Clearly, inhibitor arcs affect whether transitions are enabled, whereas reset arcs affect the result of firing an enabled transition.
Definition 6 (Enabling and firing a transition in a reset/inhibitor net). Let $N = (P, T, F, R, I)$ be a reset/inhibitor net, $t \in T$ and $M, M' \in \mathbb{M}(N)$. Transition $t$ is enabled at $M$, denoted as $M[t]$, iff $M \geq \bullet t$ and $M \upharpoonright I(t) = 0$. If a transition is enabled at $M$, it may fire, which results in a marking $M'$, where $M' = (M - \bullet t) \upharpoonright (P \setminus R(t)) + t$.

Mutatis mutandis, the definitions of liveness and boundedness for marked reset/inhibitor nets are the same as defined for marked Petri nets.

2.3. A visa application example

To show the usefulness of reset and inhibitor arcs and to motivate the need for reduction rules, we use the visa application example. This example is loosely based on the description of the visa application for general skilled migration to Australia, which can be found on the Internet (see http://www.immi.gov.au). Fig. 1 shows a possible BPMN [14] model for this process.

The process starts when a visa application is received (rva) and ends when the applicant cancels the request (ca), the processing is stopped due to non-responsiveness of the applicant (sp), or when the application is finalized in a proper way (fa). In the latter case, the visa can either be granted (gv) or denied (dv), in which case the applicant is notified (na). Typically, after the application has been received, a case officer opens a file for the applicant (oaf), processes application fees (paf), and performs an initial assessment (pia). If the application is complete (c), the officer continues with the main assessment (pma). Otherwise (nc), the officer sends an acknowledgment letter to the applicant (sal) and requests further information (rfi). After having completed the main assessment, the case officer might request for more information (rmi), or she/he makes a decision (mdc or md). However, before making the decision, the officer first needs to check whether circumstances have changed (ccc). If the officer receives the requested additional information (rri), the main assessment is performed again. However, the applicant could wait too long to supply the office with the requested information (time expiry, te), in which case the officer needs to decide (dte) whether to stop processing the application (sp) or to continue anyway (caw).

While the application is being processed, but before the decision is made, two events might occur. First, an applicant may decide to withdraw his/her application (receive withdraw, rw); second, an applicant can notify the officer that his/her circumstances (for example, change of address) have changed (receive circumstance change, rcc). On receipt of this notification, the officer archives the circumstance change (acc) and creates/updates a circumstance change document (ccd).
The example contains both cancellation regions as blocking behavior. If the processing of an application is stopped, then the entire case needs to be canceled. Furthermore, if the inner block is done, then the possibility to receive and archive a circumstance change needs to be canceled. Finally, if a circumstance changes was received and archived, then the officer needs to take this change into account and the md task should be blocked.

Fig. 2 shows the result after converting the BPMN model into a reset/inhibitor net in a straightforward manner. As usual, circles represent places, squares represent transitions, and black dots represent tokens. As mentioned before, the arc with the empty circle at the end is an inhibitor arc, whereas the arc with the double-headed arrow is a reset arc. For sake of readability, we have emphasized these arcs. The dashed area represents a cluster of places that is being reset by the same
set of transitions. For sake of readability, we have replaced all reset arcs from these places to these transitions by one reset area.

The conversion has replaced BPMN nodes by place-bordered fragments, while BPMN edges were replaced by (black) transitions. For sake of the analysis of both boundedness and liveness [16], we have added the transition new to the resulting reset/inhibitor net. The resulting net contains 54 places and 58 transitions, while its state space contains 199 states. Fig. 2 shows two things:

1. When using real-life languages like BPMN, there is a need to model blocking and cancellation.
2. Petri nets resulting from translations may be large and have a huge state space. We have encountered workflow models with hundreds of activities resulting in Petri nets with thousands of transitions.

3. Reduction rules

In this section, we present eight reduction rules for reset/inhibitor nets. The underlying rules for marked Petri nets presented in this section are based on existing reduction rules for Petri nets and free-choice nets [8,11], and are therefore not original as such, rather the contribution is in the identification of the conditions under which they can be applied in the presence of reset and inhibitor arcs.

For sake of clarity, we decided to first present applicable conditions for marked Petri nets, before extending these rules for marked reset/inhibitor nets. We also show that these reduction rules preserve liveness and boundedness. The style of presentation is inspired by [11].

3.1. Fusion of Series Transitions (FST)

Using the Fusion of Series Transitions (FST) rule, we can reduce two transitions and a place to one transition. Thus, we can effectively remove a place and a transition. For the rule to be applicable, we need the two transitions and place to be in a series. The place acts as a kind of transient place for the output places of the series. Tokens from this transient place can effectively remove a place and a transition. For the rule to be applicable, we need the two transitions and place to be in a series. The place acts as a kind of transient place for the output places of the series. Tokens from this transient place can be considered as being ghost tokens in these output places: These ghost tokens are not there yet, but they may arrive at any moment. If something happens to these ghost tokens, it should happen to the tokens in the transient place. For transitions that consume these ghost tokens, this means that the intermediate transition (the second one in the series) should fire first.

**Definition 7** (FST rule for marked Petri nets: $\phi_{\text{FST}}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1)$ and $N_2 = (P_2, T_2, F_2)$. $(S_1, S_2) \in \phi_{\text{FST}}$ if there exists a place $p \in P_1$, two transitions $t, u \in T_1$, and a transition $v \in T_2 \setminus T_1$ such that:

**Conditions on $S_1$:**

1. $p \cdot = \{t\}$ (t is the only input of $p$)
2. $p \bullet = \{u\}$ (u is the only output of $p$)
3. $u = \{p\}$ (p is the only input of u)
4. $t \bullet \cap u \bullet = \emptyset$ (any output of t is not an output of u and vice versa)

**Construction of $S_2$:**

5. $P_2 = P_1 \setminus \{p\}$
6. $T_2 = (T_1 \setminus \{t, u\}) \cup \{v\}$
7. $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2))) \cup (\bullet \cdot \times \{v\}) \cup \{(v \times ((t \cdot \bullet \cup u \cdot \bullet \setminus \{p\}))

8. For all $x \in P_2$: $M_2(x) = \begin{cases} M_1(x) & \text{if } x \notin u \bullet \\ M_1(x) + M_1(p) & \text{if } x \in u \bullet \end{cases}$

**Theorem 1** (The $\phi_{\text{FST}}$ rule is boundedness and liveness preserving). Let $S_1$ and $S_2$ be two marked Petri nets such that $(S_1, S_2) \in \phi_{\text{FST}}$. Then $S_1$ is bounded iff $S_2$ is bounded, and $S_1$ is live iff $S_2$ is live.

**Proof.** The $\phi_{\text{FST}}$ rule is boundedness and liveness preserving [8].

Fig. 3 shows both the $\phi_{\text{FST}}$ and the upcoming $\phi_{\text{RI}}$ rule. As usual, transitions are visualized using squares and places by circles. The places and transitions that are relevant for the rule at hand are white inside, whereas the places and transitions in their allowed environment are gray inside. To visualize that this environment might include multiple places and/or transitions, we have stacked three places and/or transitions. Thus, in Fig. 3, transition t may have additional output places, and transition u is not allowed to reset any place (as there is no reset place for u in the allowed environment) nor should it inhibit any place. For the $\phi_{\text{FST}}$ rule presented in Definition 7, we simply have to ignore every reset and inhibitor arc.

As mentioned before, this rule holds as we can consider the tokens in place p to be matched by ghost tokens in the output places of transition u. These ghost tokens have not arrived yet, but they will arrive when needed by firing u. From this observation, the restrictions on reset arcs and inhibitor arcs follow in a straightforward way:
• Transition $u$ should not be inhibited. As $u$ needs to be enabled if $p$ is marked, any inhibitor should be ineffective: If $u$ is inhibited by some place $x$, then $x$ should be empty when $p$ is marked. In some cases this can be checked using only structural properties. However, it is not possible to formulate simple requirements, and using a state space to check whether transition $u$ is not effectively inhibited clearly defeats the purpose of the reduction rule. Therefore, we simply require that $u$ has no inhibitor arcs.

• Transition $u$ should not reset. We cannot tell exactly when $u$ may fire. However, the effect of these resets should always be the same: If in some firing sequence $u$ resets some place $x$ by removing 2 tokens, then in any other firing sequence it should reset $x$ by removing 2 tokens. As this too is hard to check using only structural properties, and constructing the state space defeats the rule’s purpose, we do not allow $u$ to have any reset arcs.

• Place $p$ and the output places of transition $u$ should inhibit the same set of transitions. Assume that place $x$ is an output place of $u$ and that $x$ inhibits some transition $y$. As a result, transition $y$ should be inhibited if $x$ contains ghost tokens. Therefore, place $p$ should inhibit $y$, and thus, every output place of $u$ should inhibit $y$ (as these places may contain ghost tokens of $p$ as well).

• Place $p$ and the output places of transition $u$ should all be reset by the same set of transitions. Assume that place $x$ is an output place of $u$ and that $x$ is being reset by some transition $y$. As $y$ also resets the ghost tokens in $x$, it should also reset $p$, and thus, all other output places of $u$.

**Definition 8** (FST rule for marked reset/inhibitor nets: $\phi_{\text{FST}}^R$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets, where $N_1 = (P_1, T_1, F_1, R_1, I_1)$ and $N_2 = (P_2, T_2, F_2, R_2, I_2)$. $(S_1, S_2) \in \phi_{\text{FST}}^R$ if there exists a place $p \in P_1$, two transitions $t, u \in T_1$, and a transition $v \in T_2 \setminus T_1$ such that:

**Extension of the $\phi_{\text{FST}}$ rule:**

1. $((P_1, T_1, F_1), M_1), ((P_2, T_2, F_2), M_2)) \in \phi_{\text{FST}}$ (Note that, by definition, the $t, u, v$, and $p$ mentioned in this definition have to coincide with the $t, u, v$, and $p$ as mentioned in the definition of $\phi_{\text{FST}}$.)

**Conditions on $R_1$:**

2. For all $q \in u$:
   - $R_1^+(p) = R_1^+(q)$ (p is being reset by the same transitions as every output place of u is)
   - $R_1(u) = \emptyset$ (u does not reset)

3. $R_1(u) = \emptyset$ (u is not inhibited)

**Conditions on $I_1$:**

4. For all $q \in u$:
   - $I_1^-(p) = I_1^-(q)$ (p inhibits the same transitions as every output place of u does)
   - $I_1(u) = \emptyset$ (u is not inhibited)

5. $I_1(u) = \emptyset$ (u is not inhibited)

**Construction of $R_2$:**

6. For all $x \in T_2$:
   - $R_2(x) = \begin{cases} R_1(x) \setminus \{p\} & \text{if } x \neq v \\ R_1(t) \setminus \{p\} & \text{if } x = v \end{cases}$

**Construction of $I_2$:**

7. For all $x \in T_2$:
   - $I_2(x) = \begin{cases} I_1(x) \setminus \{p\} & \text{if } x \neq v \\ I_1(t) \setminus \{p\} & \text{if } x = v \end{cases}$

We now present two lemmas that show that occurrence sequences in $N_1$ and $N_2$ correspond to each other. These lemmas are then used to prove that the $\phi_{\text{FST}}^R$ rule preserves liveness and boundedness.

**Lemma 1** (Under the $\phi_{\text{FST}}^R$ rule, sequences in $S_1$ correspond to sequences in $S_2$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets such that $(S_1, S_2) \in \phi_{\text{FST}}^R$, let $\sigma_1 \in T_1^*$ and $M'_1 \in M(P_1)$ be such that $M_1 \xrightarrow{\sigma_1} M'_1$, and let $\sigma_2 = \alpha(\sigma_1)$, where $\alpha \in T_1^* \rightarrow T_2^*$ removes every occurrence of $u$ from the sequence, and replaces every occurrence of $t$ with $v$.

![Fig. 3. Fusion of Series Transitions.](image-url)
Then $M_2 \xrightarrow{N_2,\sigma_2} M'_2$, where

$$M'_2(x) = \begin{cases} M'_1(x) + M'_1(p) & \text{if } x \in u \setminus N_1 \\ M'_1(x) & \text{if } x \not\in u \setminus N_1 \end{cases} \quad (1)$$

**Proof.** By induction on the length of $\sigma_1$.

**Base** Assume $\sigma_1 = \epsilon$. Clearly, $M_1 \xrightarrow{N_1,\sigma_1} M_1$ and $M_2 \xrightarrow{N_2,\sigma_2} M_2$. Eq. 1 holds, as $\phi_{\text{FST}}^{\text{RI}}$ implies $\phi_{\text{FST}}$.

**Step** Assume the lemma holds for some $\sigma_1$, let $M'_1$ be such that $M_1 \xrightarrow{N_1,\sigma_1} M'_1$, and let $M'_2$ be such that $M_2 \xrightarrow{N_2,\alpha(\sigma)} M'_2$. We prove that it also holds if we extend $\sigma_1$ by one transition.

- First, assume that we extend $\sigma_1$ by $t$. As $t$ and $v$ have the same preset, we can extend $\alpha(\sigma_1)$ by $v$. $t$ adds a token to place $p$, whereas $v$ adds tokens to its postset, which does not violate Eq. (1).
- Second, assume that we extend $\sigma_1$ by $u$. It is obvious that $u$ does not violate Eq. (1).
- Third, assume that we extend $\sigma_1$ by $x$, where $x \in P_1 \setminus \{t, u\}$. As all places in $M'_2$ contain at least as many tokens as their counterparts in $M'_1$ (Eq. (1)), we know that $x$ is enabled in $S_2$ at $M'_2$ as well, provided it is not inhibited by a place in the postset of $u$ (as these places may contain more tokens in $M'_2$ than in $M'_1$). However, due to Eq. (1), a transition inhibited in $S_2$ at $M'_2$ would have been inhibited in $S_1$ at $M'_1$ as well. \(\square\)

**Lemma 2** (Under the $\phi_{\text{FST}}^{\text{RI}}$ rule, sequences in $S_2$ correspond to sequences in $S_1$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets such that $(S_1, S_2) \in \phi_{\text{FST}}^{\text{RI}}$, let $\sigma_2 \in T_2$ and $M'_2 \in M_2(P_2)$ be such that $M_2 \xrightarrow{N_2,\alpha(\sigma_2)} M'_2$, and let $\sigma_1 = \beta(\sigma_2)$, where $\beta \in T_2 \rightarrow T_1$ replaces every occurrence of $v$ with $tu$:

- $\beta(\epsilon) = \epsilon$,
- $\beta(v\sigma) = tu\beta(\sigma)$, and
- $\beta(x\sigma) = x\beta(\sigma)$, where $x \in T_2 \setminus \{v\}$.

Then $M_1 \xrightarrow{N_1,\sigma_1} M'_1$, where

$$M'_1(x) = \begin{cases} 0 & \text{if } x = p \\ M'_2(x) & \text{if } x \in P_2 \end{cases} \quad (2)$$

**Proof.** By induction on the length of $\sigma_2$.

**Base** Assume $\sigma_2 = \epsilon$. Clearly, $M_2 \xrightarrow{N_2,\sigma_2} M_2$ and $M_1 \xrightarrow{N_1,\sigma_1} M_1$. Eq. (2) holds, as $\phi_{\text{FST}}^{\text{RI}}$ implies $\phi_{\text{FST}}$, which also implies $M_1(p) = 0$.

**Step** Assume the lemma holds for some $\sigma_2$, let $M'_2$ be such that $M_2 \xrightarrow{N_2,\alpha(\sigma_2)} M'_2$, and let $M'_1$ be such that $M_1 \xrightarrow{N_1,\beta(\sigma_2)} M'_1$. We prove that this also holds if we extend $\sigma_2$ by one transition.

- First, assume that we extend $\sigma_2$ by $v$. It is obvious that $t$ is enabled in $S_1$ at $M'_1$, and that $u$ is enabled after having fired $t$. Furthermore, the combination of $tu$ and $v$ does not violate Eq. (2).
- Second, assume that we extend $\sigma_2$ by $x$ such that $x \in T_2 \setminus \{v\}$. Again, it is obvious that $x$ is enabled in $S_1$ at $M'_1$, and that $x$ does not violate Eq. (2). \(\square\)

From these lemmas, preservation of liveness and boundedness follow in a straightforward way.

**Theorem 2** (The $\phi_{\text{FST}}^{\text{RI}}$ rule preserves liveness).

**Proof.** Assume $(S_1, S_2) \in \phi_{\text{FST}}^{\text{RI}}$ such that $S_1$ is live and $S_2$ is not live (a similar proof can be constructed for the other case as well). Thus, in $S_2$ we can reach a marking $M'_2$ from which some transition $t$ cannot be enabled. Due to Lemma 2, we can reach a marking $M'_1$ in $S_1$ such that its where-clause holds. As $S_1$ is live, we can reach a marking $M'_1$ in $S_1$ through some occurrence sequence $\sigma_1$ such that $t$ is enabled. Due to Lemma 1 we can thus reach a marking $M'_2$ in $S_2$ such that its where clause-holds. Obviously, $t$ should be enabled in $M'_2$. Thus, $S_2$ has to be live as well. \(\square\)

**Theorem 3** (The $\phi_{\text{FST}}^{\text{RI}}$ rule preserves boundedness).
Fig. 4. Necessity of condition 2: $p$ and $r$ need to be reset by the same transitions.

Fig. 5. Necessity of condition 5: $u$ should not be inhibited.

Proof. Assume $(S_1, S_2) \in \phi_{\text{RI}}$ such that $S_1$ is bounded and $S_2$ is not bounded (a similar proof can be constructed for the other case as well). Thus, for every $b \in \mathbb{N}$ we can reach a marking $M'_2$ in $S_2$ in which some place $p$ contains more than $b$ tokens. Due to Lemma 2, we can reach a marking $M'_1$ in $S_1$ such that $M'_1(p) = M'_2(p)$. Thus $S_1$ has to be unbounded as well.

We end this section on the $\phi_{\text{RI}}$ rule with two examples that show the necessity of conditions 2 and 5. For the conditions 3, 4, 6 and 7, such examples can be given as well, but to save space we have chosen not to do so.

Fig. 4 shows why any place in the postset of $u$ and $p$ need to be reset by the same set of transitions. In the example, place $r$ is in the postset of $u$ and is reset by transition $x$, but $p$ is not reset by $x$. The leftmost net is unbounded (places $p$ and $r$ are unbounded), while the rightmost net is bounded.

Fig. 5 shows why transition $u$ should not be inhibited. The leftmost net is not live, while the rightmost net is live. Note that in both nets the inhibitor arc from $q$ to $t$ is redundant, but it is added to show that even when $t$ and $u$ are inhibited by the same (non-empty) set of places the rule does not apply. Note that adding a transition-place pair in-between place $q$ and transition $w$ removes the problem, as firing this new transition would remove the inhibition for transition $u$ in the leftmost net. However, to take such a situation into account would lead to very complex rules (as we have to take additional places and transitions into account), and for now we decided to keep it simple and to stick to the original rules as much as possible.

The remaining reduction rules all preserve liveness and boundedness. For the Fusion of Series Places, the required proofs for this claim are similar to the proofs presented for the current, Fusion of Series Transitions rule, whereas for the other rules the required proofs are simpler. As these proofs add little or nothing to the paper, we decided not to include them.

3.2. Fusion of Series Places (FSP)

Using the Fusion of Series Places (FSP) rule, we can reduce two places and one transition to one place. Thus, like the Fusion Series Transitions rule, this rule also effectively removes a transition and a place. However, the Fusion of Series Places may be applicable in situations where the Fusion of Series Transitions rule is not. Again like the Fusion of Series Transitions rule, this rule is applicable if the places and transitions are in a series, and again we can use the concept of ghost tokens to explain the rule. Tokens which reside in the first place of the series can be considered to be ghost tokens for the second place. If some transition needs to consume these ghost tokens, the intermediate transitions should fire first, replacing the ghost tokens by real ones. (See Fig. 6.)

Definition 9 (FSP rule for marked Petri nets: $\phi_{\text{FSP}}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1)$ and $N_2 = (P_2, T_2, F_2)$. $(S_1, S_2) \in \phi_{\text{FSP}}$ if there exist two places $p, q \in P_1$, a transition $t \in T_1$, and a place $r \in P_2 \setminus P_1$ such that:
Conditions on $S_1$:
1. $\bullet t = \{p\}$  
   ($p$ is the only input of $t$)
2. $t \bullet = \{q\}$  
   ($q$ is the only output of $t$)
3. $p \bullet = \{t\}$  
   ($t$ is the only output of $p$)
4. $\bullet p \cap \bullet q = \emptyset$  
   (any input of $p$ is not an input of $q$ and vice versa)

Construction of $S_2$:
5. $P_2 = (P_1 \setminus \{p, q\}) \cup \{r\}$
6. $T_2 = T_1 \setminus \{t\}$
7. $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2))) \cup (\{\bullet p \cup \bullet q\} \setminus \{t\}) \cup \{r\} \times Q$  
8. For all $x \in P_2$: $M_2(x) = \begin{cases} M_1(x) & \text{if } x \neq r \\ M_1(p) + M_1(q) & \text{if } x = r \end{cases}$

Tokens in place $p$ are matched by ghost tokens in place $q$. Again, these tokens have not arrived yet, but they will materialize if needed by firing transition $t$. Again, the restrictions on reset arcs and inhibitor arcs follow in a straightforward way from this observation:

- Transition $t$ should not be inhibited. As it is hard to check on ineffective inhibitor arcs, we simply require that $t$ has no inhibitor arcs.
- Transition $t$ should not reset. As it is hard to check that every reset has the same effect, we simply require that $t$ has no reset arcs.
- Place $p$ should be inhibited by the same set of transitions as place $q$.
- Place $p$ should be being reset by the same set of transitions as place $q$.

Definition 10 (FSP rule for marked reset/inhibitor nets: $\phi^{RI}_{\text{FSP}}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets, where $N_1 = (P_1, T_1, F_1, R_1, I_1)$ and $N_2 = (P_2, T_2, F_2, R_2, I_2)$. $(S_1, S_2) \in \phi^{RI}_{\text{FSP}}$ if there exist two places $p, q \in P_1$, a transition $t \in T_1$, and a place $r \in P_2 \setminus P_1$ such that:

Extension of the $\phi_{\text{FSP}}$ rule:
1. $((P_1, T_1, F_1, M_1), ((P_2, T_2, F_2), M_2)) \in \phi_{\text{FSP}}$
2. (Note that, by definition, the $p, q, t, r$ mentioned in this definition have to coincide with the $p, q, t, r$ as mentioned in the definition of $\phi_{\text{FSP}}$.)

Conditions on $R_1$:
2. $R_1(t) = \emptyset$  
   ($t$ does not reset)
3. $R_1^{-1}(p) = R_1^{-1}(q)$  
   ($p$ and $q$ are being reset by the same transitions)

Conditions on $I_1$:
4. $I_1(t) = \emptyset$  
   ($t$ does not have inhibitor arcs)
5. $I_1^{-1}(p) = I_1^{-1}(q)$  
   ($p$ and $q$ have the same set of inhibitor arcs)

Construction of $R_2$:
6. For all $x \in T_2$: $R_2(x) = \begin{cases} (R_1(x) \setminus \{p, q\}) \cup \{r\} & \text{if } \{p, q\} \cap R_1(x) \neq \emptyset \\ R_1(x) & \text{if } \{p, q\} \cap R_1(x) = \emptyset \end{cases}$

Fig. 6. Fusion of Series Places.
Construction of $I_2$:

\[ I_2(x) = \begin{cases} 
I_1(x) \setminus \{p, q\} \cup \{r\} & \text{if } \{p, q\} \cap I_1(x) \neq \emptyset \\
I_1(x) & \text{if } \{p, q\} \cap I_1(x) = \emptyset 
\end{cases} \]

3.3. Fusion of Parallel Transitions (FPT)

Using the Fusion of Parallel Transitions (FPT) rule, we can reduce a number of transitions to one transition. This rule is applicable if all transitions have the same set of input places and the same set of output places. Clearly, all transitions are enabled at the same time, and all have the same effect. (See Fig. 7.)

**Definition 11** (FPT rule for marked Petri nets: $\phi_{\text{FPT}}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1)$ and $N_2 = (P_2, T_2, F_2)$. $(S_1, S_2) \in \phi_{\text{FPT}}$ if there exist transitions $V \subseteq T_1$ where $|V| \geq 2$, an arbitrary transition $t \in V$, and a transition $v \in T_2 \setminus T_1$ such that:

**Conditions on $S_1$:**

1. for all $x, y \in V$: \( \bullet x = \bullet y \) (input places for all transitions in $V$ are identical)
2. for all $x, y \in V$: \( x = y \bullet \) (output places for all transitions in $V$ are identical)

**Construction of $S_2$:**

3. $P_2 = P_1$
4. $T_2 = (T_1 \setminus V) \cup \{v\}$
5. $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2)))) \cup (\bullet t \times \{v\}) \cup (\{v\} \times \bullet t) \cup (\bullet t \times \{v\}) \cup (\{v\} \times \bullet t)$
6. $M_2 = M_1$

As the transitions should be enabled at the same time, either all or none should be inhibited. As a check on ineffective inhibitor arcs is hard, we simply require the transitions to have the same set of inhibitors. Furthermore, their effects should be identical. As it is hard to check when the effect of a transition that resets some place is identical to the effect of a transition that does not reset that place, we simply require that every transition resets the same set of places.

**Definition 12** (FPT rule for marked reset/inhibitor nets: $\phi_{\text{FPT}}^{RI}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets, where $N_1 = (P_1, T_1, F_1, R_1, I_1)$ and $N_2 = (P_2, T_2, F_2, R_2, I_2)$. $(S_1, S_2) \in \phi_{\text{FPT}}^{RI}$ if there exist transitions $V \subseteq T_1$ where $|V| \geq 2$, an arbitrary transition $t \in V$, and a transition $v \in T_2 \setminus T_1$ such that:

**Extension of the $\phi_{\text{FPT}}$ rule:**

1. \(((P_1, T_1, F_1, R_1, I_1), (P_2, T_2, F_2, R_2, I_2)) \in \phi_{\text{FPT}}^{RI}\)

(Note that, by definition, the $V$ and $v$ mentioned in this definition have to coincide with the $V$ and $v$ as mentioned in the definition of $\phi_{\text{FPT}}$.)

**Condition on $R_1$:**

2. for all $x, y \in V$: \( R_1(x) = R_1(y) \) (all transitions in $V$ reset the same places)

**Condition on $I_1$:**

3. for all $x, y \in V$: \( I_1(x) = I_1(y) \) (all transitions in $V$ share the same set of inhibitor arcs)

**Construction of $R_2$:**

4. for all $x \in T_2$: \( R_2(x) = \begin{cases} 
R_1(x) & \text{if } x \neq v \\
R_1(t) & \text{if } x = v 
\end{cases} \)

**Construction of $I_2$:**

4. for all $x \in T_2$: \( I_2(x) = \begin{cases} 
I_1(x) \setminus \{p, q\} \cup \{r\} & \text{if } \{p, q\} \cap I_1(x) \neq \emptyset \\
I_1(x) & \text{if } \{p, q\} \cap I_1(x) = \emptyset 
\end{cases} \)
3.4. Fusion of Parallel Places (FPP)

Using the Fusion of Parallel Places (FPP) rule, we can reduce a number of places to one place. This rule is applicable if all places have the same set of input transitions and the same set of output transitions. Clearly, only those places among these places that initially contains the fewest tokens can become empty and can, hence, disable any transitions. Therefore, all other places are implicit and can be removed. (See Fig. 8.)

**Definition 13** (FPP rule for marked Petri nets: $\phi_{FPP}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1)$ and $N_2 = (P_2, T_2, F_2)$. $(S_1, S_2) \in \phi_{FPP}$ if there exist places $Q \subseteq P_1$ where $|Q| \geq 2$, an arbitrary place $p \in Q$ and a place $q \in P_2 \setminus P_1$ such that:

**Conditions on $S_1$:**

1. for all $x, y \in Q$: $x = y$ (input transitions for all places in $Q$ are identical)
2. for all $x, y \in Q$: $x = y$ (output transitions for all places in $Q$ are identical)

**Construction of $S_2$:**

1. $P_2 = (P_1 \setminus Q) \cup \{q\}$
2. $T_2 = T_1$
3. $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2))) \cup (q \times [q]) \cup ([q] \times q) N_1$
4. $F_2 = \left\{ \begin{array}{ll}
M_1(x) & \text{if } x \neq q \\
\min_{y \in Q} M_1(y) & \text{if } x = q
\end{array} \right.$

When adding reset arcs and inhibitor arcs, we should guarantee that the other places remain implicit. Thus, these other places should always contain at least as many tokens as the place we keep. Therefore, any transition that resets any other place, should also reset the place we keep. However, we may not allow the other places to become unbounded if the place we keep is bounded. For this reason, we require that any transition that resets the one place, should also reset all other places. As a result, we require that all places in $Q$ are being reset by the same set of transitions. However, for inhibitor arcs something similar does not hold. Fig. 9 shows an example where the rightmost parallel place contains more tokens than the leftmost place. Note that we should not initialize the place in the right-hand net with two tokens, as this would allow for two firings of transition $v$. In both marked nets transition $v$ can fire once, but the left-hand net is then dead, whereas the right-hand net is not. Clearly, this is caused by the fact that a token was left in the right-most parallel place.
should not result in a new marking. Thus:

Condition on $R$: ELT rule for marked Petri nets: Let $s_1 = (N_1, M_1)$ and $s_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1, R_1, I_1)$ and $N_2 = (P_2, T_2, F_2, R_2, I_2)$. $(s_1, s_2) \in \phi_{\text{ELT}}$ if there exist places $Q \subseteq P_1$ where $|Q| \geq 2$ and a place $q \in P_2 \setminus P_1$ such that:

Extension of the $\phi_{\text{FPP}}$ rule:

1. $((P_1, T_1, F_1), (P_2, T_2, F_2), M_1, M_2) \in \phi_{\text{FPP}}$

(Note that, by definition, the $Q$ and $q$ mentioned in this definition have to coincide with the $Q$ and $q$ as mentioned in the definition of $\phi_{\text{FPP}}$.)

Condition on $R_1$: (1) for all $x, y \in Q$: $R_1^{-1}(x) = R_1^{-1}(y)$ (all places in $Q$ are being reset by the same transitions)

Condition on $I_1$: (2) for all $x \in Q$: if $M_1(x) > \min_{y \in Q} M_1(y)$ then $I_1^{-1}(x) = \emptyset$

(only places with a minimal initial marking may inhibit transitions)

Construction of $R_2$: (3) for all $x \in T_2$: $R_2(x) = \begin{cases} (R_1(x) \setminus Q) \cup \{q\} & \text{if } R_1(x) \cap Q \neq \emptyset \\ R_1(x) & \text{if } R_1(x) \cap Q = \emptyset \end{cases}$

Construction of $I_2$: (4) for all $x \in T_2$: $I_2(x) = \begin{cases} (I_1(x) \setminus Q) \cup \{q\} & \text{if } I_1(x) \cap Q \neq \emptyset \\ I_1(x) & \text{if } I_1(x) \cap Q = \emptyset \end{cases}$

3.5. Elimination of Self-Loop Transitions (ELT)

Using the Elimination of Self-Loop Transitions (ELT) rule, we can remove a Self-Loop Transition, that is, a transition that has only one input place and only one output place, and for which the input place and the output place are identical. Clearly, firing the transition does not have any effect. Thus, removing the transition does not affect boundedness. However, removing it could affect liveness, as it can be the only non-live transition. To prevent this, we require that the input/output place has at least one additional input transition. (See Fig. 10.)

Definition 15 (ELT rule for marked Petri nets: $\phi_{\text{ELT}}$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1)$ and $N_2 = (P_2, T_2, F_2)$. $(S_1, S_2) \in \phi_{\text{ELT}}$ if there exists a place $p \in P_1$, and a transition $t \in T_1$ such that:

Conditions on $S_1$:

1. $\bullet t = \{p\}$ (p is the only input place of t)
2. $\bullet t = \{p\}$ (p is the only output place of t)
3. $|\bullet p| \geq 2$ (p has at least one additional input transition)

Construction of $S_2$:

4. $P_2 = P_1$
5. $T_2 = T_1 \setminus \{t\}$
6. $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2)))$
7. $M_2 = M_1$

Clearly, after reset arcs and inhibitor arcs have been added, $t$ should be enabled at some point in time, and its effect should not result in a new marking. Thus:
any place that inhibits \( t \) should be emptiable while place \( p \) is marked, and
- \( t \) should not reset any place.

As the first requirement is hard to obtain from the structure of the marked net, we simply require that \( t \) is not inhibited at all.

**Definition 16** (ELT rule for marked reset/inhibitor nets: \( \phi_{RI}^{ELT} \)). Let \( S_1 = (N_1, M_1) \) and \( S_2 = (N_2, M_2) \) be two marked reset/inhibitor nets, where \( N_1 = (P_1, T_1, F_1, R_1, I_1) \) and \( N_2 = (P_2, T_2, F_2, R_2, I_2) \). \((S_1, S_2) \in \phi_{RI}^{ELT} \) if there exists a place \( p \in P_1 \cap P_2 \) and a transition \( t \in T_1 \) such that:

**Extension of the \( \phi_{ELT} \) rule:**

1. \( ((P_1, T_1, F_1, M_1), ((P_2, T_2, F_2, M_2)) \) \( \in \phi_{ELT} \)
   (Note that, by definition, the \( t \) and \( p \) mentioned in this definition have to coincide with the \( t \) and \( p \) as mentioned in the definition of \( \phi_{ELT} \).)

2. \( R_1(t) = \emptyset \) (\( t \) does not reset)

3. \( I_1(t) = \emptyset \) (\( t \) does not have any inhibitor arcs)

4. for all \( x \in T_2 \) : \( R_2(x) = R_1(x) \)

5. for all \( x \in T_2 \) : \( I_2(x) = I_1(x) \)

3.6. Elimination of Self-Loop Places (ELP)

The Elimination of Self-Loop Places (ELP) rule can be used to remove places that are always marked. As a result, these places never disable any output transition.

**Definition 17** (ELP rule for marked Petri nets: \( \phi_{ELP} \)). Let \( S_1 = (N_1, M_1) \) and \( S_2 = (N_2, M_2) \) be two marked Petri nets, where \( N_1 = (P_1, T_1, F_1) \) and \( N_2 = (P_2, T_2, F_2) \). \((S_1, S_2) \in \phi_{ELP} \) if there exists a place \( p \in P_1 \) \( \setminus \) \( P_2 \) such that:

**Conditions on \( S_1 \):**

1. \( p \bullet = \bullet p \) (the inputs of \( p \) are also its outputs)
2. \( M_1(p) \geq 1 \) (\( p \) is marked at \( M_1 \))

**Construction of \( S_2 \):**

3. \( P_2 = P_1 \setminus \{p\} \)
4. \( T_2 = T_1 \)
5. \( F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2))) \)
6. for all \( x \in P_2 \) : \( M_2(x) = M_1(x) \)

Clearly, place \( p \) should not inhibit any transition. Furthermore, to ensure that the place is always marked, any transition that removes tokens from this place should put at least one token back. Thus, any transition that resets \( p \) should also put a token in \( p \). However, a transition that resets \( p \) and puts a token in \( p \) does not need to consume a token using a normal input arc. Therefore, the \( \phi_{RI}^{ELP} \) rule is not a simple extension of the \( \phi_{ELP} \) rule. This is illustrated by the two sets of transitions in Fig. 11.

**Definition 18** (ELP rule for marked reset/inhibitor nets: \( \phi_{RI}^{ELP} \)). Let \( S_1 = (N_1, M_1) \) and \( S_2 = (N_2, M_2) \) be two marked reset/inhibitor nets, where \( N_1 = (P_1, T_1, F_1, R_1, I_1) \) and \( N_2 = (P_2, T_2, F_2, R_2, I_2) \). \((S_1, S_2) \in \phi_{RI}^{ELP} \) if there exists a place \( p \in P_1 \) \( \setminus \) \( P_2 \) such that:
Conditions on $S_1$:
(1) $p \subseteq \bullet p$ (the outputs of $p$ are also inputs)
(2) $M_1(p) \geq 1$ ($p$ is marked at $M_1$)

Condition on $R_1$:
(3) $R_1^+(p) \cup \bullet p = \bullet p$ (every reset transition or output transition should also be an input transition)

Condition on $I_1$:
(4) $I_1^+(p) = \emptyset$ ($p$ does not inhibit any transition)

Construction of $S_2$:
(5) $P_2 = P_1 \setminus \{p\}$
(6) $T_2 = T_1$
(7) $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2)))$
(8) For all $x \in P_2$: $M_2(x) = M_1(x)$

Construction of $R_2$:
(9) For all $x \in T_2$: $R_2(x) = R_1(x) \cap P_2$

Construction of $I_2$:
(10) $I_2 = I_1$

3.7. Abstraction (A)

Like the Fusion of Series Transitions rule and the Fusion of Series Places rule, using the Abstraction rule, we can remove a place and a transition. In fact, the Abstraction rule is in some way a mix of both fusion rules. As is the case for the two fusion rules, this rule can be understood using the concept of ghost tokens. Basically, we can replace a place-transition pair (where the place is the only input of the transition and the transition is the only output of the place) by a number of arcs connecting every input transition of the place to every output place of the transition, thus bypassing both. Any token in the place is matched by ghost tokens in the output places of the transition. If needed, these ghost tokens can materialize by firing the transition. (See Fig. 12.)

Definition 19 (Abstraction rule for marked Petri nets: $\phi_A$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked Petri nets, where $N_1 = (P_1, T_1, F_1)$ and $N_2 = (P_2, T_2, F_2)$. $(N_1, N_2) \in \phi_A$ if there exists places $Q \subseteq P_1 \cap P_2$, a place $s \in P_1 \setminus Q$, transitions $U \subseteq T_1 \cap T_2$, and a transition $t \in T_1 \setminus U$ such that:

Conditions on $S_1$:
(1) $\bullet t = \{s\}$ ($s$ is the only input of $t$)
(2) $s \bullet = \{t\}$ ($t$ is the only output of $s$)
(3) $\bullet s = U$ (transitions in $U$ are input transitions for $s$)
(4) $t \bullet = Q$ (places in $Q$ are output places for $t$)
(5) $(\bullet \times \bullet) \cap F = \emptyset$ (any input of $s$ is not connected to an output of $t$ and vice versa)

Construction of $S_2$:
(6) $P_2 = P_1 \setminus \{s\}$
(7) $T_2 = T_1 \setminus \{t\}$
(8) $F_2 = (F_1 \cap ((P_2 \times T_2) \cup (T_2 \times P_2))) \cup (\bullet s \times \bullet t)$
(9) For all $x \in P_2$: $M_2(x) = \begin{cases} M_1(x) & \text{if } x \notin Q \\
M_1(x) + M_1(s) & \text{if } x \in Q \end{cases}$

As for the fusion rules, transition $t$ should not be inhibited, as this might disable the firing of $t$. Also likewise, $t$ should not reset any place. As for the Fusion of Series Transitions rule, place $s$ should inhibit the same set of transitions as every output place of $t$ does, and it should be reset by the same set of transitions that reset every output place of $t$.

Definition 20 (Abstraction rule for marked reset/inhibitor nets: $\phi_{AI}^R$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets, where $N_1 = (P_1, T_1, F_1, R_1, I_1)$ and $N_2 = (P_2, T_2, F_2, R_2, I_2)$. $(S_1, S_2) \in \phi_{AI}^R$ if there exists places $Q \subseteq P_1 \cap P_2$, a place $s \in P_1 \setminus Q$, transitions $U \subseteq T_1 \cap T_2$, and a transition $t \in T_1 \setminus U$ such that:

Extension of the $\phi_R$ rule:
(1) $((P_1, T_1, F_1), (P_2, T_2, F_2), (M_1, M_2)) \in \phi_A$
(Note that, by definition, the $s$, $t$, $Q$, and $U$ mentioned in this definition have to coincide with $s$, $t$, $Q$, and $U$ as mentioned in the definition of $\phi_A$.)
Conditions on $R_1$:
(2) $R_1(s) = R_1(q)$, for every $q \in Q$ (s is being reset by transitions that reset Q)
(3) $R_1(t) = \emptyset$ (t does not reset)

Conditions on $I_1$:
(4) $I_1(s) = I_1(q)$, for every $q \in Q$ (s inhibits the same transitions as every place from Q does)
(5) $I_1(t) = \emptyset$ (t is not inhibited by any place)

Construction of $R_2$:
(6) for all $x \in T_2$: $R_2(x) = R_1(x) \cap P_2$

Construction of $I_2$:
(7) for all $x \in T_2$: $I_2(x) = I_1(x) \cap P_2$

3.8. Reset Reduction (R)

If a transition $u$ resets a place that inhibits it, then the reset arc is clearly redundant: The transition can only fire if the place is empty. Note that the place may optionally be an input place and/or output place of $u$ as well (if it is an input place as well, $u$ will be dead of course, but the rule still applies). (See Fig. 13.)

Definition 21 (Reset Reduction rule for marked reset/inhibitor nets: $\phi_{RI}^R$). Let $S_1 = (N_1, M_1)$ and $S_2 = (N_2, M_2)$ be two marked reset/inhibitor nets, where $N_1 = (P_1, T_1, F_1, R_1, I_1)$ and $N_2 = (P_2, T_2, F_2, R_2, I_2)$. $(S_1, S_2) \in \phi_{RI}^R$ if there exists a place $u \in P_1 \cap P_2$ and a transition $t \in T_1 \cap T_2$ such that:

Conditions on $S_1$:
(1) $p \in R_1(u) \cap I_1(u)$

Construction of $S_2$:
(2) $P_2 = P_1$
(3) $T_2 = T_1$
(4) $F_2 = F_1$
(5) for all $x \in T_2$: $R_2(x) = \begin{cases} R_1(x) & \text{if } x \neq u \\ R_1(x) \setminus \{p\} & \text{if } x = u \end{cases}$
(6) $I_2 = I_1$
(7) $M_2 = M_1$
3.9. The visa application example

To illustrate what we can achieve by reduction, we have applied the rules defined earlier to the visa example shown in Fig. 2. Fig. 14 shows the resulting net.

As a result of applying the reduction rules on the visa example, the number of places is reduced from 54 to 14, and the number of transitions drops from 58 to 18. As a result, the size of the state space is reduced from 199 to 17. This will make it easier to determine both boundedness and liveness and other related properties such as soundness [16]. Note that the visa example only has a few states. Hence the reduction in states is not very spectacular. However, for more realistic examples the state space grows very rapidly. As shown in different studies (e.g., [17,18]) reduction rules can reduce the state space dramatically. Given the generic character of the rules presented in this paper, it is obvious that similar results can be obtained for Petri nets extended with reset arcs and inhibitor arcs.

4. Related work

In the general area of reset nets, Dufourd et al.’s work has provided valuable insights into the decidability of various properties of reset nets including reachability, boundedness and coverability [2,3]. The use of backwards coverability tech-
niques to analyze reset nets is discussed in [5,4]. In [7,19], the extension to Petri nets using inhibitor arcs is mentioned. The reachability problem of Petri nets with one inhibitor arc is studied in [20] and shown to be decidable. The reachability problem of Petri nets with at least two inhibitor arcs is shown to be undecidable in [6]. In [9], the author focuses on expressiveness of inhibitor arcs and shows that an extension of coverability tree construction could be used as an analysis technique for Petri nets with inhibitor arcs. In [21], the authors propose an extension to colored Petri nets with inhibitor arcs that supports both zero-testing inhibitors and threshold inhibitors.

A number of authors have investigated reduction rules for Petri nets and for various subclasses of Petri nets. In Murata's paper [8], six reduction rules are presented for Petri nets and this set of rules has been used as a starting point for the rules mentioned in this paper. In the book by Desel and Esparza [11], a set of reduction rules are proposed for free-choice Petri nets while preserving well-formedness. Berthelot [10,22] presents a set of reduction rules for general Petri nets, which later on were extended to Time Petri nets by Sloan and Buy [12]. However, these reduction rules do not take cancellation or blocking into account. As part of our work on workflow verification, a set of soundness preserving reduction rules for YAWL models was presented in [23]. In this technical report similar ideas are applied to YAWL workflows with cancellation regions and OR-joins, but without blocking behavior.

In [18] a comprehensive comparison of the different state-space reduction techniques is reported. Here, different reduction techniques are applied to both artificial and real-life examples. The study shows that the classical Petri net reduction rules (for nets without reset arcs and inhibitor arcs) perform very well and are able to reduce state-spaces dramatically. This illustrates the practical relevance of the results reported in this paper.

5. Conclusion

It is widely known that applying reduction rules to large Petri nets can dramatically reduce the time it takes to perform all kinds of analyses. Typically, a reduction rule will decrease the number of elements under consideration by removing certain transitions and/or places in the net while preserving some interesting properties. For Petri nets extended with reset arcs and inhibitor arcs, the existing Petri net reduction rules do not apply since each rule can be invalidated by the presence of reset arcs and/or inhibitor arcs.

In this paper, we have presented a set of eight reduction rules for reset/inhibitor nets that are liveness and boundedness preserving. These reduction rules are generic and easy to implement. We used an example to illustrate the applicability of our approach. The results allow for potentially spectacular reductions of the state space and, therefore, facilitate a more efficient analysis of reset/inhibitor nets.

In our view these results are highly relevant because real-life modeling languages such as UML, BPEL, BPMN, etc. have features such as cancellation and blocking that correspond directly to reset and inhibitor arcs. Moreover, model translations typically introduce lots of “dummy” transitions that do not correspond to real events. The results presented in this paper therefore potentially allow for a substantial speed-up of any form of Petri-net-based analysis using languages such as UML, BPEL and BPMN as a starting point.

Finally, the reduction rules can also be applied in the reverse direction to create correctness preserving construction rules. One could make a graphical editor that allows for the incremental construction of process models such that in each step of the design process the model is correct by construction.
